ter-relation of Abdominal Diseases

by ELEMER FORRAI, M D (Budapest), L R C P (Edin)

with a Foreword by SIR ARTHUR HURST, M A, D M (Oxon), F R C P

d on a record of 300 cases of chronic gall-bladder disease spread over several generations of certain families, hly interesting monograph demonstrates that the central control organ associated with many gastro-enterological ors is the liver The author emphasises the allergic manifestations produced, and makes valuable suggestions ring early recognition and avoidance of complications He incorporates a review of the literature, as well esults of his own studies

SCALPEL BLADES

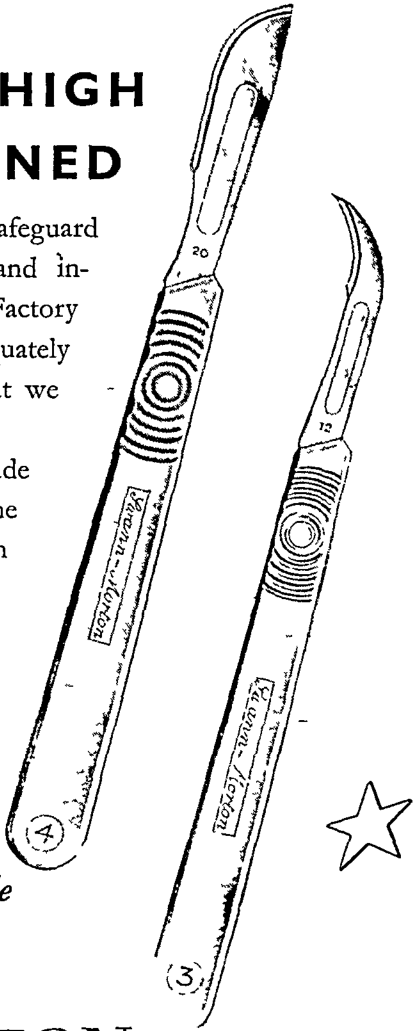
NO SCARCITY . . . HIGH QUALITY MAINTAINED

Our declared policy of doing our utmost to safeguard surgery against shortage of scalpel blades and increased prices has been completely successful Factory arrangements have been developed, output adequately increased, and working costs so regulated that we are still able to supply at pre-war prices

In peace-time, the Swann Morton Scalpel Blade had already established itself in the face of the keenest foreign competition, because of its high quality As a result, in May 1939 we were able to drastically reduce our price from 6/6 to 3/- per dozen To-day, when foreign competition is withdrawn, our policy remains unchanged

The highest quality possible

. . . . the lowest price possible



SWANN MORTON

SCALPEL BLADES

3/- PER DOZEN 1-gross lots 33/ per gross 5-gross lots 31/6 per gross 10 gross lots and over 30/- per gross Handles 5/ each (Nos 3 and 4) *Through all Surgical Instrument Manufacturer*

W R SWANN & CO LTD , PENN WORKS, BRADFIELD ROAD, SHEFFIELD

SAFE AND CERTAIN

BIOLOGICAL THERAP

★ ANTIPEOL OINTMENT

contains sterile vaccine filtrates (antivirus) of all the common strains of STAPHYLOCOCCI, STREPTOCOCCI and B. PYOCYANEUS
lanoline zinc-ichthyol base

STOPS SEPTIC DEVELOPMENT WHILST HEALING

SPECIFIC AGAINST the micro organisms causing abscesses boils eczema dermatitis, erysipelas, hæmorrhoids, impetigo, ulcers and all inflamm
cutaneous affections ANTIPEOL LIQUID for infections of the ear, septic cavities and suppurating wounds

★ OPHTHALMO-ANTIPEOL

contains, in a semi fluid base, the sterile vaccine filtrates of STAPHYLOCOCCI, STREPTOCOCCI, B PYOCYANEUS, PNEUMOCOCCI FRAENKEL AND GONOCOCCI
INDICATIONS Conjunctivitis, blepharitis, keratitis, dacriocystitis, and all inflammatory conditions and lesions of the eye

★ RHINO-ANTIPEOL

a nasal immunising cream, contains Antipeol Liquid as well as the antivirus and autolysins of PNEUMOCOCCI, PNEUMO BACILLI, ENTEROCOCCI, M CATARRHALIS, B PFEIFFER, and calmative and decongestive ingredients
INDICATIONS Coryza, rhinitis, hay fever, catarrh, influenza, colds and other naso pharyngeal infections

★ ENTEROFAGOS (ORAL)

polyvalent bacteriophages specific against 132 strains of micro organisms common to infections of the gastro intestinal tract, kidneys and bladder
RAPIDLY EFFECTIVE RESULTS in enteritis dysentery colitis, diarrhœas, B coli infections, typhoid and para typhoid fevers, and other intestin
and para intestinal infections Oral administration No reactions, No shock

★ DETENSYL

vegeto—polyhormonic hypotensor ensures gentle and regular reduction of arterial tension
INDICATIONS High blood pressure, arthritis, arteriosclerosis palpitation, ocular and auditory troubles of hypertension No contra indications

ENLARGED SECOND EDITION

Neuro-ophthalmology

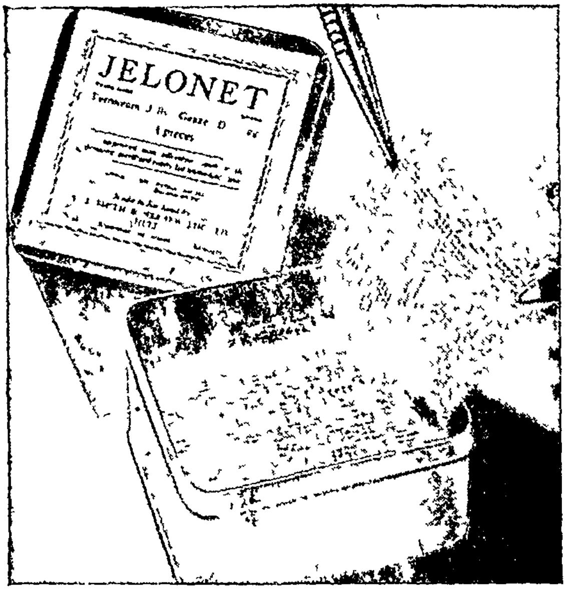
by R. LINDSAY REA BSc MD MCh FRCS

★ For the second edition the author has made emendations in the original text, but has discussed the latest developments of his subject in an extensive Appendix of 100 pages This has been divided under the same chapter headings as the first edition Many additional illustrations and 3 new plates in colour have been included The original bibliography and index have been enlarged

The new edition makes a great advance on the original work, itself described by THE LANCET as a valuable and informative book, encyclopædic in its scope'

Pages xxiii + 688 ● 196 illustrations ● 24 plates ● 50s net

HEINEMANN (MEDICAL BOOKS) LTD 99 GREAT RUSSELL ST LONDON WC1



'JELONET' PETROLEUM JELLY GAUZE DRESSING

is made from a specially woven open-mesh gauze evenly saturated with petroleum jelly and Balsam of Peru and is packed in sealed containers of 24 dressings sterilised ready for immediate use Jelonet is indicated for Skin-Grafts Compound Fractures Burns etc as a non-adherent dressing to promote granulation The open-mesh dressing encourages free escape of discharge and ensures ventilation for skin-grafts and young epithelium with minimum trauma to granulations Uniform saturation with petroleum jelly prevents serious rise of temperature due to toxic absorption secondary dermatitis of the surrounding skin arising from irritating discharge and also permits ready extrusion from deep wounds

Obtainable through your usual Surgical Supplier 5/-d per tin of 24 dressings Special Prices available to Hospitals Made by the makers of Elastoplast and Cellona

T J SMITH & NEPHEW LTD HULL

Raising the Metabolic Rate

Three Methods

CASES of depressed metabolism are, of course, common occurrence in general practice, particularly among convalescents

It is very seldom, however, that a practitione wishes to resort to such drastic methods of raisin the metabolic rate as intravenous injection of thyroxi or the administration by mouth of compounds of th nitro-phenol group Indeed, both these measure are usually contra-indicated, owing to the fact tha either is liable to involve severe interference with the normal mechanism of the body

For this reason, the practitioner generally prefer the third of the accepted methods of stimulating the metabolic rate namely, the prescription of *food* such as meat extracts, home-made broths, etc

It is a matter of some importance, therefore, t know that *one* of the accepted meat preparations is outstandingly effective in raising the metabolic rate It is Brand's Essence

After the ingestion of Brand's Essence, there is sharp increase in the heat output, reaching a pea at the end of half an hour, and still appreciabl six hours later

Accordingly, Brand's Essence may be prescribed with confidence for cases of depressed metabolism It will be found palatable even when all other foods are distasteful, and it has a further advantage in tha it stimulates the appetite It will be found of specia convenience in those cases in which the patient cannot tolerate sufficient protein *It is still sold a pre-war prices*

"TANNOL"

TRADE MARK BRAND

for BURNS & SCALDS

The Tannic Acid Treatment in an Improved Form

Tannol is a combination of Tannic Acid (10%) with an emulsion of Acriflavine (an antiseptic which is itself of value in the treatment of burns—*vide* N H Mummery, "The Lancet," March 25th, 1933)

TANNOL treatment of Burns and Scalds combines the antiseptic properties of Acriflavine with the healing and non-scarring characteristics of Tannic Acid On re-dressing with Tannol the newly formed tissue is not damaged, thus ensuring rapid healing

TANNOL keeps indefinitely and is always ready for immediate use Supplied in convenient bottles for the surgery and the home

Wheat-starch conversion by BENGER'S FOOD

Benger's Food is a specially prepared wheaten powder containing adequate quantities of natural pancreatic enzymes of which the proteolytic enzyme known as trypsin and the starch converting amylases are of first importance The wheaten powder serves two highly important functions (1) it acts as conveyor of these enzymes (2) in preparation of the Food by the admixture of hot milk it is converted into dextrins, dextri-maltoses and maltose

When the hot milk meets the cold mixture the resulting temperature is correct for the enzyme action Within two minutes the starch of the wheaten powder has been made soluble so that prepared Benger's Food contains only 0 5% of insoluble starch As the digestion proceeds the trypsin modifies the milk protein so that when it comes in contact with the gastric juices, it separates into fine flocculi, as compared to the heavy tough curd formed by milk itself Both actions take place whilst the Food is too hot to drink

For Infants, Invalids and those suffering from severe digestive weakness, the time for pre-digesting Benger's Food should be extended to 15 minutes and upwards to 45 minutes At the end of this period the wheaten powder is converted to dextrins, dextri-maltoses and maltose, and the milk proteins modified so that the finest possible curd is formed on contact with the gastric juices

Sole Manufacturers **BENGER'S FOOD LTD**
Holmes Chapel Cheshire, Eng

The Benger Laboratories are always at the disposal of the medical profession in any of their dietetic problems
Physicians samples of Benger's Food are always available

Influenza

In rheumatoid conditions, in myalgia, lumbago and influenzal infections, Bengué Balsam usually produces rapid relief from pain

Through local decongestive action and systemic salicylate influence, Bengué Balsam quickly allays joint and muscle discomfort Swelling subsides, and greater motion becomes possible, resolution is promoted and restoration of function is hastened

The systemic action of Bengué Balsam, produced by cutaneous absorption of Methyl Salicylate, never leads to the gastric irritation so often encountered in the oral administration of Salicylates

A generous sample will be sent upon request

Let us now praise famous men

. . . and particularly those who have responded to our appeal not to hoard cylinders of Oxygen and Nitrous Oxide in excess of immediate requirements

To them we say thank you for making easier our task of ensuring that ample reserves of both gases are instantly available day and night all over the country to meet any emergency

To the others—and we regret to have to record that such still there are—we repeat

The total volume of gas that The British Oxygen Company Ltd supplies for medical purposes is only a fraction of what it supplies to Industry It holds ample reserve stocks at strategic points all over the British Isles It can, and will, take all your Medical requirements in its stride, provided only that you do your part and

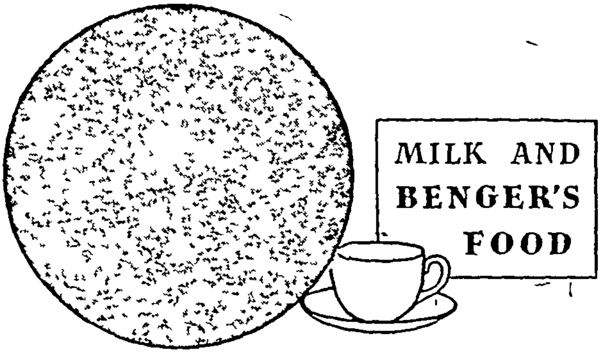
ILLUSTRATING

the Breakdown of Milk Protein

by Benger's Food

Milk, as soon as it comes in contact with the gastric juice, forms heavy curds. Many children and adults cannot properly digest these curds, and they cause pain and discomfort to persons with impaired digestion For this reason many who most need milk are denied its great benefits



As soon as hot milk is poured on to Benger's Food the active pancreatic enzymes, held dormant in its wheaten base become active Within a very short

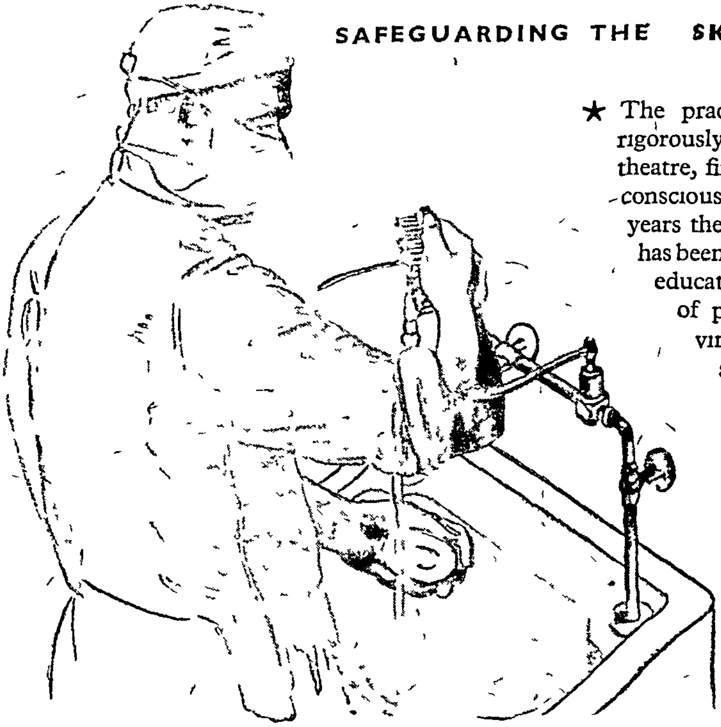
SAFEGUARDING THE SKIN FROM INFECTION



★ The practice of surgical cleanliness, so rigorously observed in the operating theatre, finds a reflection in the everyday consciousness of the layman Of recent years the use of Wright s Coal Tar Soap has been growing—largely as a result of the education of the public in the elements of protection against infection By virtue of its well-known antiseptic and antipruritic properties Wright's Coal Tar Soap has been used and recommended by Doctors for more than 70 years Its therapeutic property is combined with a gentleness of action acceptable to the most sensitive skin

WRIGHT'S COAL TAR SOAP PROTECTS WHILE IT CLEANSES

"An After-Fitting Service to meet changing Aural Conditions"

OUR SERVICE TO DOCTORS AND THEIR DEAF PATIENTS

— NUMBER TWO —

IN prescribing "Ardente" for your deaf patients when an aid becomes necessary, you are safe because they can obtain service in most important towns throughout Great Britain—to meet any change in their aural condition As an additional safety factor, each "Ardente" is covered by its maker's guarantee

There are a full range of "Ardente" types—electrical and non-electrical, bone-conduction, granule, valve, and phantom—which are individually suited, after testing by Aurameter, to the needs of each case—no expense being incurred until hearing satisfactorily

R. H. Dent
M Inst. P I

Particulars gladly sent and Tests are made at Aurists' Doctors' patients Hospitals, or any of our addresses

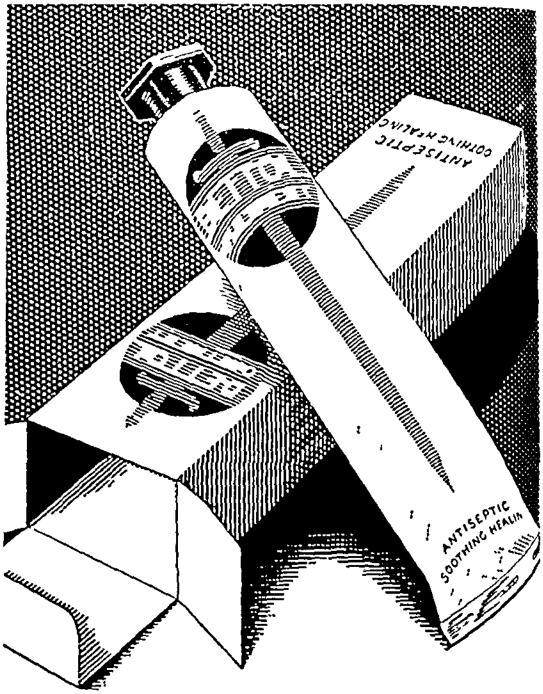
And now Dettol Ointment

The difficulties of compounding an unguent with a clinically antiseptic action will be well understood But the makers of Dettol have now prepared such an ointment—Dettol Ointment It embodies the active germicidal principle of Dettol

The widest use of this new ointment is to prevent secondary infection in those skin conditions where an ointment form is preferable to a liquid, and to protect the surrounding skin in the presence of suppuration Clinical reports give evidence of ample bactericidal activity and of the healing properties of the emollient base



Packed in Tubes Also in 1-lb Jars for Hospital and Surgery use.

DIAGNOSIS AND TREATMENT OF SECONDARY SHOCK

A STUDY OF 24 CASES

BY

A KEKWICK
M B Camb, M R C P
CAPTAIN R A M C

W D'A MAYCOCK
M D McGill
CAPTAIN R A M C

H L MARRIOTT
M D Lond, F R C P
LIEUT COLONEL R A M C

L E H WHITBY, C V O,
M C, M D Camb, F R C P
COLONEL R.A M C (T A)

(*From the Army Blood-t[illegible]usion Service*)

SINCE this investigation began we have treated over 100 cases of primary or secondary shock The present report, which concerns 24 cases of secondary shock that were selected for systematic study, provides data sufficient to justify tentative conclusions that can be tested by other observers with more material at their disposal The findings support the opinion and recommendations expressed in the current M R C memorandum (1940)

CASE-RECORDS

CASE 1 —Male, aged 60 Seen 2½ hours after injury Right leg completely destroyed from 2 in below knee and small hole in abdominal wall, though splinter had not entered peritoneal cavity Tourniquet had been applied 15 min after injury and morphia gr ¼ given 15 min later Mentally dull but rational, no pain, no thirst, pallor ++, cyanosis of lips and fingers ++, no sweating, very cold Hb finger 100%, vein 104%, hæmatocrit 40% Pulse impalpable, B P not recordable

After 1 pint plasma in 15 min P 108, B P 40/? *After* 2nd pint plasma in 15 min P 110, B P 60/40, Hb finger 70%, vein 60% hæmatocrit 25 5% After 3rd pint plasma in 12 min P 160, B P 80/50 After 4th pint plasma in 23 min P 120, B P 105/55, Hb finger 47%, vein 45%, hæmatocrit 19% Had by now greatly improved in colour, pain in legs and abdomen Had to wait for admission to theatre on account of congestion, during which time B P *fell to 80/50 and* 1 pint blood administered Left theatre with B P 100/70 Amputation of leg through upper third of thigh, abdominal wall opened and f b removed Anæsthetic G O E After 24 hours condition excellent, P 78, B P 115/70, Hb finger 52%

CASE 2 —Male, aged 26 Seen 3 hours after injury Wound in left loin 8 in in diameter, multiple superficial wounds, abdominal *wound, small* wound right shoulder Morphia gr ½ 40 min after injury Warmed with electric blanket for 45 min before transfusion, Mentally clear and rational, pain slight, thirst ++, pallor ++, cyanosis slight, no sweating, hands very cold P 86, B P 50/30

After 1 pint blood in 20 min P 92, B P 70/60 After 2nd pint blood in 20 min P 94, B P 80/75 After 3rd pint blood in 20 min P 100, B P 95/75, colour greatly improved, operation started debridement, intestinal resection At end of operation P 90, B P 90/70 After 24 hours P 100, B P /80, general condition good

ASE 3 —Male, aged 24 Seen 3½ hours after injury iple small injuries of back, legs and arms, gaping hole in buttock 9 in in diameter, buttock almost completely ved, perforating wound left wrist joint Morphia gr ¼ ours after injury Warmed with electric blanket for 1¼ before transfusion Mentally clear, pain ++, thirst +, ++, cyanosis ++, sweating slight, T 95° F, P 82, 0/30, Hb ear 120%, vein 100%, hæmatocrit 43%

r 1 pint plasma in 20 min P 100, B P 70/40 After t plasma in 20 min P 120, B P 80/45 After 3rd pint *in 20 min* P 128, B P 100/55, Hb, ear 80% Greatly d but pallor still extreme, 1 pint blood given in P 120, B P 100/60 Started bleeding from buttock, blood given in 30 min During operation of debride- which much bleeding 2 further pints blood adminis ach in 15 min Anæsthetic G O E After operation B P 112/70 After 24 hours general condition good, B P 115/80, [illegible] 8%

4 —Male aged 20 Seen 4 hours after injury wounds and compound fracture of both legs Mentally *clear, not in great pain, thirst* ++, pallor ++, cyanosis of nails, no sweating, complained of cold Pulse impalpable, B P 60/30 Morphia administered

After 2 pints blood each taking 10 min P 120, B P 115/65 Great improvement in general condition, cyanosis disappeared, treated by warming and 1 pint blood by drip until turn came for theatre During operation received 1 more pint blood and left theatre with P 118, B P 90/50

CASE 5 —Male Seen 2 hours after injury Severe scalp wounds, one ear off, extensive laceration left arm and probably intrathoracic injury Mentally clear, colour ashen grey, complained of painful breathing, P 155, B P 70 Warmed and morphia gr ¼ administered

After 4 bottles *plasma in an hour P 120, B P 120/70*

CASE 6 —Male, aged 23 Seen 4⅓ hours after injury Simple fracture left femur compound fracture right femur, fracture left clavicle, left Colles's fracture, abrasions head Morphia gr ½ given Mentally clear, pain ++, thirst ++, colour normal, sweating nil, not cold B P 75/60, P 120

After 1 pint plasma in 8 min P 104, B P 105/80 After 2nd pint plasma in 10 min P 92, B P 120/90 Anæsthetic begun Had 3rd *pint plasma by drip occupying 45 min* At end of operation P 132, B P 145/50 Patient collapsed and died shortly afterwards Was found to have multiple injuries, including fractured base, blood in c s f, fracture ribs, small tears in liver and spleen, hæmorrhage into right suprarenal

CASE 7 —Male, aged 30 Seen 2½ hours *after injury* Very large wound in back, involving right kidney Had received morphia gr ¼ 2 hours after injury Apathetic, pain ++, thirst ++, pallor +++, sweating slight, cyanosis slight, cold, shivering Pulse uncountable, B P 95/60, Hb vein 120%, hæmatocrit 43%

After 1 pint plasma in 5 min P 150, B P 100/65 After 2nd pint plasma *in 10 min P 120, B P 105/70,* Hb vein 94%, hæmatocrit 33% After 3rd pint plasma in 30 min P 140, B P 110/80, Hb vein 74%, hæmatocrit 26% Sent for operation of debridement and ligature during which received 1 pint blood, 2 more pints blood given next day After 48 hours condition fairly good, P 120, B P 110/80, but passing much blood in urine Died 3 days later

CASE 8 —Male, aged 29 Seen 2 hours after injury Shrapnel wounds both legs, compound *comminuted* fractures right and left tibia and fibula, machine gun bullet wound in left loin, not penetrating abdomen Tourniquets applied to both thighs, given morphia gr ¼ an hour after injury and again an hour later Put to bed with foot raised and warmed Mentally clear, pain +, thirst +, pallor +, cyanosis of nails, sweating ++, cold, pulse impalpable, B P 60/40

One hour later, after 1 *pint plasma in 10* min pulse flickering, B P 70/? After 2nd pint plasma in 15 min P 120, B P 90/55 After 3rd pint plasma in 50 min P 110, B P 115/75 Taken to operating theatre and on table for 2 hours, during which fourth pint of plasma administered by drip Condition rapidly deteriorated when injured limbs were manipulated Died few hours afterwards

CASE 9 —*Male* aged 16 Seen 1½ hours after injury Compound fracture right thigh, much laceration and pulping of bone, and compound fracture lowest third left leg, much laceration and pulping of bone, gross swelling of both limbs above site of injury Morphia gr ⅓ 45 min after injury Mentally clear, pain ++ when moved, thirst ++, pallor ++, cyanosis of lips +, sweating slight, cold P 112, B P 80/55, Hb finger 90%, *ear* 95%

After 1 pint plasma in 12 min P 108, B P 95/70 After 2nd pint plasma in 20 min P 108, B P 95/70 After 3rd pint plasma in 45 min P 108, B P 110/75 Taken to operating-theatre for double amputation, during which 1 pint blood given in 28 min and 1 pint plasma as drip Left theatre with P 104, B P 120/70 Uninterrupted recovery

CASE 10 —Male, aged 26 Seen 2¾ hours after being hi on back by lump of rock, very large bruise left kidney region with great swelling left flank, and ? left pneumothora Given morphia gr ⅓ an hour after injury Mentally clear, pain in chest +, thirst +, no pallor cyanosis +, sweating slight temperature normal, P 130, B P 70/55, Hb vein 97%, hæmatocrit 37%

After 1 pint plasma in 15 min P 108, B P 100/50, Hb vei 84%, hæmatocrit 33 5% After 1 pint blood in 3 hours B P 125

After 24 hours condition satisfactory

Here is shown the effect of rennet on Benger's Food prepared by Formula I and adjusted to pH 4 6

A short monograph on this subject has been published by Benger's Food Ltd., Holmes Chapel, Cheshire, and is available to any member of the medical profession forwarding his or her card.

entally clear, pain +, thirst ++, cyanosis slight, no eating, cold, P 144, B P 70/50

After 1 pint plasma in 10 min P 140, B P 85/65 After d pint plasma in 20 min B P 100/70 After 1 pint blood in) min P 100, B P 105/80 A further pint blood adminis- ired as slow drip during operation Died 5 hours later obably from bilateral hæmothorax

PRIMARY AND SECONDARY SHOCK

Primary shock due to psychogenic and neurogenic influences is common among air-raid casualties which each hospital soon after their injury Most are at least ightened and shaken These, from primary shock lone, may exhibit pallor sweating, feeble pulse and ow blood-pressure or even be unconscious Differentiation of primary from secondary shock is easy with xtremes of injury, when the wounding is of such severity hat immediate transfusion is obviously required and elay would be dangerous, or when there are no wounds nd transfusion would be both unnecessary and foolish But in intermediate cases differentiation is only possible by allowing a period of observation, the degree to which rest in the recumbent head-low position combined with warmth and morphia produces improvement will depend on how far the symptoms are due to primary shock If at the end of an hour the blood-pressure is still below 100 mm Hg some degree of secondary shock s probable and transfusion should be done before an anæsthetic is given But if within the hour the blood-pressure rises and stays above 100 mm. Hg it may be assumed even though a normal figure has not been completely reached, that the shock was mainly primary and that transfusion is not necessary for resuscitation, though it may well be required during operation. The blood-pressure should be taken every 15 min so that patients who are losing way may be transfused without delay In order to carry out this work satisfactorily a special resuscitation ward must be established between the reception point and the operating-theatre All the 24 cases here described had either wounds so severe as to brook no delay in instituting transfusion or a blood-pressure which failed to recover to 100 mm Hg with rest, warmth and morphia

ASSESSMENT OF SEVERITY

In general we have found that the blood-pressure is the most reliable measurable factor for assessing the severity of secondary shock and that other clinical manifestations are variable and not quantitative

The *pulse-rate* has not always been as rapid as it is generally assumed to be in severe secondary shock nor does it regularly rise in proportion as the blood-pressure falls Thus 5 cases (2 3, 15, 16, 22) had rates of 86, 82, 104, 92 70 with systolic blood-pressures of 55 mm Hg or less and one (12), who proved in a follow-up to be a hypertensive, had a pulse-rate of 58 with a systolic pressure of 95 mm In the remainder the pulse-rate ranged from 110 to 155 and did not appear to bear any constant relation to the blood-pressure The response of the pulse-rate to transfusion was even more irregular, in strong contrast to the response of the blood-pressure

The *mental state* in 17 cases was clear and rational This point which is of great practical importance—that the mental state is no index of the severity of shock—was repeatedly stressed by observers in the war 1914–18 who found that in the absence of head injury a clear normal mind was usual in secondary shock even within a few minutes of death

As to *pain*, all of our 24 patients had had morphia, pain is recorded as absent in 4 slight or moderate in 8 and severe in 11, and was not recorded in 1

Colour-changes are common but in no way quantitative, 22 out of 24 patients showed obvious pallor and most had also cyanosis of the lips and nails Extreme pallor in association with a relatively high blood-pressure suggests intense compensatory vasoconstriction

The general *temperature* of all severe cases is invariably subnormal and the extremities feel cold This feature, however, depends greatly on the atmospheric conditions, the exposure during transit and the efficiency of the methods for warming *Sweating* was present in 15 cases but the amount was by no means related to the degree of shock

The records of *blood-pressure* are shown in table I With two exceptions (7 12) the most severely wounded had the lowest blood-pressures The two exceptions are instructive Case 12 was found in a follow-up to be a hypertensive having a blood-pressure of 160/120 when lying in bed, her initial blood-pressure of 95 mm was therefore a relatively large fall from normal Case 7, though severely wounded and exsanguinated nevertheless appeared to be capable of maintaining his blood-pressure at 95 mm Hg by intense vasoconstriction Our experience of over 100 cases shows that this feature is a real entity especially in young subjects seen soon after wounding The phenomenon is suggested by an intense pallor in association with an unexpectedly high blood-pressure In the particular case here recorded this view is supported by the response to transfusion, in that 3 pints caused a rise of only 15 mm in blood-pressure though it much improved the man's general condition Apart from these two cases there has been a remarkable correlation between the reduction in blood-volume and the fall in blood-pressure while restoration of blood-volume by transfusion has been found to be associated with a proportional recovery in blood-pressure (tables I and II)

TREATMENT AND ASSESSMENT OF RECOVERY

It is generally accepted that the symptoms of secondary shock are caused largely by gross reduction in blood-volume which leads to an inefficient circulation, later to irreversible tissue-cell changes owing to malnutrition, and finally to circulatory failure The obvious treatment is to restore blood-volume Information is required as to the best fluid for this purpose, when to transfuse in what amount and at what rate From the physiological aspect whole blood is needed by those whose reduction in blood-volume is due mainly to whole-blood loss and this is usually the case with those who are neither burned nor crushed and who are seen soon after wounding before complex hæmatological changes have occurred We have analysed our cases in relation to fluid, time, amount and rate but have used more plasma than blood with a view to obtaining information as to its efficiency as a volume-restoring fluid

It has already been indicated that transfusion without delay should be carried out on those with serious wounds and a dangerously low blood-pressure, on those whose blood-pressure does not recover to 100 mm Hg within an hour of routine resuscitation and on those whose blood-pressure observed at 15-min intervals continues to decline during the resuscitation hour Blood-pressure readings have been taken during the course of transfusion after every 540 c cm of blood or plasma transfused Table I sets out the observed results and a detailed analysis shows that a rise of 10–20 mm Hg is obtained after each 540 c cm transfused, the average figure for the series for each successive bottle up to five being 19 1, 11 6, 16 4, 18 3 and 16 7 mm This table in conjunction with table II suggests that in order to obtain a systolic blood-pressure of 100 mm Hg or over it was necessary to transfuse not less than 50% of the calculated blood-loss which may amount to 1000–3500 c cm in severe cases of secondary shock Coincident with this improvement in blood-pressure there was a striking amelioration of other symptoms The behaviour of the pulse emphasised the unreliability of this factor for assessing improvement In a series of observations of pulse-rate before and after each 540 c cm bottle it was found that after twenty-one bottles the rate fell after twenty it rose and after four it remained unchanged Transfusion seemed to produce a fall of rate in those in whom it was initially rapid and vice versa The general response to transfusion, and particularly in the blood-pressure which appears to rise quantitatively with the amount transfused has been a constant feature of our cases

The value of blood-pressure determination has been emphasised by observations on cases in whom there has been no external evidence of severe loss of blood but detailed investigation has shown that such loss has taken place Case 16 illustrates this point The external injuries in this man of 64 were a simple fracture of one arm, two fractured ribs and a compound fracture of the femur with a small wound Five 540 c cm bottles were required during the resuscitation period and one more during operation to raise the blood-pressure to 100/55 This patient died 2½ days later from postoperative bronchopneumonia At autopsy it was found that the estimated loss to the circulation could be accounted for

CASE 11 —Male, aged 28 Seen 2½ hours after injury, compound fracture right femur, tibia and fibula, and fracture dislocation right carpus and metacarpus No tourniquet Morphia gr ¼ given Mentally clear, no pain, thirst +, pallor +, no cyanosis, sweating +, temperature normal, P ?, B P 70/50

After 1 pint blood B P 90/50 While 4 pints plasma were given in 1 hour 20 min there was progressive improvement, resulting in B P 115 though bleeding continued Excision of wounds and reduction of fractures begun Left theatre with B P 110

CASE 12 —Female, aged 50 Seen 3 hours after injury, deep wound right leg, smashed right and left feet (hanging by threads) with tourniquets still applied Morphia gr ¼ had been given 30 min after injury and repeated 2½ hours later Mentally clear, no pain, thirst +, pallor +, cyanosis +, no sweating, temperature normal, B P 95/65, P 58, Hb finger 95%

After 1 pint plasma in 20 min P 80, B P 110/80 After 2nd pint plasma in 40 min P 76, B P 118/85, Hb finger 74% During this 40 min consumed 2 cups sweet tea colour greatly improved Taken to operating theatre for amputation and débridement

After 24 hours condition good, P 80, B P 115/80 Six weeks later B P when lying in bed 160/120

CASE 13 —Male, aged 30 Seen 2 hours after injury, simple comminuted fractures of left femur, left tibia and fibula, and at lower ends of right tibia and fibula Morphia gr ½ given an hour after injury and warmed up, but condition deteriorated Tourniquet not applied until 1½ hours after injury Delirious, pain ++, pallor +++, cyanosis +, sweating +, cold, P 140, B P 60/30

After 1 pint plasma in 20 min P 110, B P 80/50 After 2nd pint plasma in 20 min P 100, B P 100/60 Condition improved, pallor less Mentally normal After 1 pint blood in 50 min P 130, B P 110/70 Taken to operating theatre for amputations, anæsthetic G O E, during operation given 1 pint blood in 60 min Left theatre with P 120, B P 110/70 After 48 hours condition satisfactory, P 92, B P 150/90

CASE 14 —Female, aged 48 Seen 5½ hours after injury, wound of right lower axillary region superficial to base of pleural cavity and right lobe of liver Given morphia gr ¼ an hour after injury and warmed for 3 hours before transfusion Mentally rational, no pain or thirst, pallor +, cyanosis +, sweating +, cold, pulse impalpable, B P unrecordable

After 2 pints plasma and 1 pint blood in 40 min colour improved but still pulseless After 1 pint plasma in 56 min pulse flickering, B P unrecordable but hands becoming pink After 1 pint plasma in 45 min pulse and B P improved progressively P 144, 132, 132, B P 80/40, 120/60, 120/60 At this stage was fit for surgical exploration, but this was not performed Patient died during next 24 hours from hæmorrhage, autopsy showed bomb fragment buried in lacerated liver

CASE 15 —Male, aged 56 Seen 4½ hours after injury, fractured transverse processes of the lumbar vertebræ, 5 fractured ribs, fractured right clavicle and rigidity of abdomen suggesting hæmoperitoneum Given morphia gr ¼ and warmed for 3 hours after injury Mentally confused, pain ++, no thirst, pallor +, no cyanosis, sweating +, warm, P 104, B P 50/35, Hb finger 110%, ear 110%, vein 108%, hæmatocrit 46%

After 1 pint plasma in 17 min P 92, B P 70/50 After 2nd pint plasma in 8 min P 100, B P 85/55, Hb finger 85%, vein 82% hæmatocrit 36% After 3rd pint plasma in 16 min P 104, B P 105/65, Hb finger 80%, vein 75%, hæmatocrit 33% Much improved, colour better, B P at two hourly intervals through night fluctuated from 95 to 110

After 24 hours condition good, P 96, B P 105/65

CASE 16 —Male, aged 64 Seen 2 hours after injury, compound fracture left femur, simple fracture left humerus, 2 fractured ribs, and the following subsequently discovered at autopsy retroperitoneal hæmorrhage, small cerebral hæmorrhage, left and right hæmothorax, small wound in spleen Mentally normal, pain moderate, thirst slight, pallor +, cyanosis slight, sweating +, cold, P 92, B P 50/?, Hb finger 94%, ear 96%, vein 106%, hæmatocrit 44%

After 1 pint plasma in 10 min P 96, B P 56/? After 2nd pint plasma in 10 min P 112, B P 72/50 After 3rd pint plasma in 15 min P 112, B P 84/50 After 4th pint plasma in 15 min P 92, B P 100/65, Hb finger 80%, ear 84% vein 72%, hæmatocrit 31% After 5th pint plasma in 40 min P 100, B P 95/60, Hb finger 62%, vein 64%, hæmatocrit 26% Taken to operating-theatre for débridement thigh and extension, colour good Left operating theatre with P 11 B P 100/50, having had 6th pint plasma in 65 min Died 2½ days later

CASE 17 —Male, aged 22 Seen 5 hours after bomb wound causing mangling of left foot, tourniquet applied Pallor ++, sweating +, P 110, B P 85/70

After 1 pint blood in 15 min P 96, B P 100/65 Taken to operating theatre with further pint of blood being administered by drip Uneventful recovery

CASE 18 —Male, aged 18 Seen 3½ hours after injury compound fractures right humerus, right leg, severe laceration left leg, multiple wounds especially round right shoulder Morphia gr ¼ given 1½ hours after injury and warmed with blankets Drowsy, pain slight, thirst ++, pallor +, cyanosis +, no sweating, cold, pulse impalpable, B P 50/35, Hb ear 92%, vein 89%

After 1 pint plasma in 10 min P 108, B P 80/45 After 2nd pint plasma in 40 min P 110, B P 95/60 After 3rd pint plasma in 30 min P 130, B P 115/70, Hb vein 55% Taken to operating-theatre with 1 pint blood by drip, extensive débridement lasting 1½ hours accompanied by much bleeding Died 6 hours after admission

CASE 19 —Female, aged 19 Seen 3 hours after injury, severe crush of both legs almost severing legs below knee, 3 puncture wounds of abdomen subsequently found to have penetrated cæcum, 1 puncture wound left thorax Morphia gr ¼ given and tourniquets applied to both thighs 30 min after injury Morphia gr ⅙ given 2 hours after injury Mentally clear, pain severe, thirst ++, pallor +, cyanosis +, sweating +, very cold, pulse impalpable, B P unrecordable

After 1 pint plasma in 10 min P impalpable, B P 40/unrecordable After 3 more pints plasma in 60 min P 144 After 1 pint blood in 45 min P 140, B P 98/unrecordable Delay in transfer to theatre and in operation, condition deteriorated although drip of blood running, blood administered in theatre but died 8 hours later

CASE 20 —Female, aged 38 Seen 8 hours after injury, multiple abrasions and large lacerated wound of face tearing both lips and whole of right side of cheek Morphia gr ¼ given 6 hours after injury Mentally clear, pain ++, thirst ++, pallor +, cyanosis slight, no sweating, extremities cold, pulse uncountable, B P 90/60 No improvement with conservative measures

After 1 pint plasma in 20 min P 124, B P 120/60 Another pint blood administered during operation for cleaning face, débridement and suture of left side of mouth General condition 2 days later excellent

CASE 21 —Male, aged 28 Seen 1½ hours after injury, blast effects to lungs, ruptured small intestine, extraperitoneal rupture of bladder, fractured pelvis, torn mesenteric vessels Morphia gr ¼ given 1 hour after injury Just conscious, pain ++, thirst ++, pallor ++, cyanosis ++, sweating moderate, stone cold, pulse impalpable, B P 50/?

After 1 pint blood in 7 min P 140, B P 60/? After 2nd pint blood in 15 min P 110, B P 80/? After 2 pints plasma in 52 min P 88, B P 110/70 During operation 2 pints blood administered slowly Survived 24 hours

CASE 22 —Female, aged 20 Seen 1¾ hours after injury, compound fracture left femur, extreme laceration left leg wound right knee and left elbow, multiple small wounds and fractured pelvis due to splinter discovered at operation Morphia gr ¼ given ½ hour after injury Mentally clear, pain +, thirst ++, pallor +, cyanosis slight, sweating ++, very cold, P 70, B P 55/?

After 1 pint plasma in 25 min B P 80/? After 2nd pint plasma in 50 min P 110, B P 50/? After 3rd pint plasma in 20 min P 110, B P 70/40 After 4th pint plasma in 35 min B P 85/40 After 1 pint blood in 60 min P 133, B P 100/60 Taken to operating theatre where 2½ pints blood given Died during operation

CASE 23 —Male, aged 52 Seen 3 hours after injury, fractured right femur, scalp wounds, severe bruising of back Morphia gr ¼ given ½ hour after injury Mentally slow, pain, thirst and pallor slight, cyanosis +, sweating +, very cold P 86, B P 60/40

After 2 pints plasma in 20 min P 88, B P 115/80 Operation, pin through tibia, 72 hours later B P 160/76

CASE 24 —Male, aged 25 Seen 3 hours after injury, compound fracture right tibia and fibula, puncture wounds both lower limbs 3 puncture wounds shoulder, puncture wound right chest Morphia gr ¼ given ½ hour after injury

The results shown in table II provide some suggestive cts concerning the phenomenon of hæmoconcentration ere is in the first place no glaring evidence that this at all marked in cases not suffering from burns or crush juries who are seen within 4½ hours of wounding in at in 7 out of 9 cases neither the capillary nor venous emoglobin before beginning treatment has been above 0% (range 94–110%) though in 2 cases the hæmoglobin is reached 120% Likewise there is no obvious evidence hæmodilution, or in 4 cases of any gross discrepancy etween venous and capillary hæmoglobin values This not to say that hæmoconcentration may not be found more advanced cases, in whom there is a longer period etween wounding and observation but it seems that e cardinal symptoms of shock can be present without uch hæmoconcentration The point can only be decided ith certainty by serial observations of hæmoglobin or ematocrit or both before treatment is begun

MISCELLANEOUS OBSERVATIONS

Plasma —The citrate plasma transfused (165 pints) to e cases recorded here as well as in our whole series has een from 10 to 56 days old The maximum given to any ne case has been six 540 c cm bottles There have een rigors in 3 cases but we have noted that almost all eriously battered and frightened casualties show some egree of shivering even before resuscitation has begun nvestigation of these cases has shown no evidence that he rigors were due to old plasma, opalescent plasma, lasma with clots or refiltered plasma

Blood or plasma —Both fluids appear to be equally fficient for restoring blood-volume in agreement with the xperimental results of Buttle, Kekwick and Schweitzer 1940) Of the 24 cases, 14 were treated with plasma lone 4 with blood alone and 6 with plasma and blood uring the resuscitation period More plasma than blood was used mainly for the purpose of collecting data, but we have formed the opinion that when the amount of transfused fluid needed reaches three 540 c cm bottles or more at least one bottle in three should be blood

Alkalosis —It is well known that shocked patients may show a varying degree of acidosis It is sometimes asked whether the amount of sodium citrate given in a large transfusion may not cause alkalosis The CO_2-combining power of the blood was determined in case 16 only this patient received in 3 hours six bottles of plasma containing approximately 28 grammes of sodium citrate The first determination was made after 18–19 g had been given and was 35 volumes % After 28 g the CO_2-combining power was 58 volumes % and early the following day 62 volumes % In this case a large amount of citrate given relatively quickly did little more than aid in the correction of an acidosis, which was probably much severer than the first of our readings indicates, and it seems unlikely that sufficient citrate to be dangerous could be given in the form of stored blood or plasma

DISCUSSION

In our experience the wounds in air-raid casualties have been multiple and severe So much so that had it not been for the promptitude with which they have been treated most of the patients recorded here would have died Only the less severe cases would drift slowly into the condition of shock which is found in battle casualties Hence these preliminary results do not necessarily contradict observations made during the war 1914–18 With these severe injuries the onset of symptoms of shock appears to be rapid and the cardinal sign of the condition a sustained and progressive lowering of the blood-pressure, is well established within a few hours Lowered blood-pressure as well as some of the other features of secondary shock (sweating, thirst pallor) are also found in primary shock It therefore seems wise to differentiate primary from secondary by allowing a period of observation during which rest in the recumbent head-low position is combined with warmth and morphia, before resorting to transfusions unless the nature of the wounds makes it obvious that the patient must have suffered the reduction in blood-volume which is the cause of the cardinal sign of secondary shock This small series emphasises that, in the earlier phases, a blood-pressure reading is the only reliable measurable observation and that pulse-rate does not always rise as blood-pressure falls Pulse-rate may be dangerously misleading

Our results justify the conclusion that reduction in blood-volume demands a reasonably quantitative replacement of protein fluid if a permanent improvement in condition is to be obtained and maintained through a perhaps severe operation In some cases the amount of fluid required is almost unbelievably large but with each successive pint transfused there should be an appreciable rise in blood-pressure of 10–20 mm Hg If this does not occur continued bleeding should be suspected Nevertheless, over-enthusiasm for quantitative replacement has its dangers An overfilled circulation is almost as great a menace as one which is dangerously emptied When hæmatological tests can be performed these supply a valuable check on the blood-pressure readings which should, whenever possible, never be omitted In the absence of blood-pressure readings attention should be paid to the volume of the pulse rather than to the rate Our impression is that 2 pints can be administered quickly without risk to a case of secondary shock with a blood-pressure below 100 mm Hg If this produces the anticipated rise in blood-pressure more can be administered with safety, though if the clinical condition has equally improved the rate of administration can be judiciously slowed But if there is no improvement in blood-pressure with 2 pints quickly administered, and continued bleeding is neither obvious nor likely, a short time should be allowed for warmth and fluid by mouth to bring about that later improvement in blood-pressure which a number of cases appear capable of effecting This is a better practice than continuing with a large rapid transfusion which carries with it a danger of pulmonary œdema if the circulation is overfilled The rate of administration after the first 2 pints requires sound clinical judgment But whenever there is clear evidence of gross loss of blood an approximately quantitative replacement should be aimed at

SUMMARY

In observing 24 cases of secondary shock a sustained and serious fall in blood-pressure in spite of simple resuscitation procedures has been found to be the one reliable clinically measurable criterion of the severity of the condition The pulse-rate is unreliable

Simple hæmatological investigations combined with plasma transfusion provide a helpful check on deductions made from blood-pressure readings with regard to the amount of fluid that needs to be transfused

As a rough rule a rise of 10–20 mm Hg can be anticipated from every 540 c cm transfused provided that bleeding has ceased and that no other causes of loss of circulatory fluid are operating

Plasma and blood are equally effective for restoring blood-volume With large transfusions 1 pint in 3 may, with advantage be blood

An approximately quantitative replacement of lost fluid is required At least half of this should be protein fluid, otherwise the restoration of blood-pressure will be only temporary and an operation will not be well borne

Transfusion should continue during any delay before operation as well as during operation especially if more blood is likely to be lost at that time

The observations reported here have been carried out by two teams consisting of a clinical observer, who recorded blood pressure, pulse rate and other clinical facts, a hæmatologist, a " transfuser " and one or two V A.D nurses These have devoted their whole time to recording results unhampered by other work Even with this generous allotment of personnel it has not been possible for any team to deal with more than 3 or 4 cases in a period of six hours We are grateful for the assistance of Captains J E Vaughan Jones, S Glaser and H Ellis, Lieutenants H W Bailie, J Dean, W Wynne-Willson, Ethel Whitby, Faith Poles and Joyce Morgan, Q.M.S Bushby and Staff-Sergeant R Blake, all of the R.A.M C , and for the facilities afforded by the staffs of the Bristol Royal Infirmary and Southmead Hospital

Un = Unrecordable N R = Not recorded
Bl = Bleeding P Bl = Probably bleeding

All transfusions were of citrated plasma except those marked * where citrated blood was given

as follows swelling of arm and thigh 1200–1500 c cm, hæmothorax 200 c cm, hæmoperitoneum 250 c cm, retroperitoneal hæmorrhage 800 c cm, external loss at time of injury ?, total 2600 c cm + In all cases seen by us it has appeared that the loss of blood-volume can be accounted for by external loss and by extravasation into the injured area In no case has there been any evidence to suggest loss of plasma in regions remote from a seat of injury

The volumes transfused (tables I and II) concern the amount necessary to relieve secondary shock prior to operation It must be remembered that delay in operation after resuscitation may be associated with deterioration in general condition first from continued blood-loss and secondly from excretion of the citrate portion of the transfused plasma or blood Resuscitated patients should be regularly observed, and if necessary transfusion should be continued during the period of delay Furthermore, most cases suffer hæmorrhage at operation No less than 15 of our 24 cases required transfusion during the operation itself

In general we have concluded that the amount to be transfused should be governed by the blood-pressure response, on which a watch should be kept during any delay as well as during operation As to rate we have formed the opinion that the first two 540 c cm bottles should be administered rapidly, each bottle occupying about 15 min Further amounts, except when the blood-pressure is dangerously low (75 mm or less), should be given at a slower rate and be governed by clinical judgment Transfusion with a blood-pressure in the region of 100 mm Hg should be continued as a drip, allowing a rate of one bottle in 3–4 hours This last procedure is a good safety measure to tide over any delay in operation, while the transfusion, administered by cannula, can accompany the patient to the theatre and then be speeded up if there is any sudden hæmorrhage or rapid deterioration in general condition

HÆMATOLOGICAL ASPECT

Of our 24 cases, 9 have been investigated hæmatologically, some more completely than others, 8 have been sufficiently examined for the serial hæmoglobin or hæmatocrit determinations to permit of calculation of the blood-volume at the beginning of treatment by the method described by Bushby, Kekwick and Whitby (1940) When the blood-volume is known a shrewd estimate of the blood-loss can be made by assuming an approximate normal blood-volume of 5½ litres for a man and 5 litres for a woman Table II shows that it is possible to sustain an acute loss of as much as 3½ litres of b and yet survive provided that reasonable restoration blood-volume is carried out quickly and adequat There can be little doubt that if these cases had suff the delay in treatment which is almost inevitable battle casualties most of them would never have reach a dressing station alive The series provides examp of both the accuracy and the fallacy of the method o estimating blood-volume As to accuracy, case 15 w examined by consecutive hæmatocrit measurement venous blood and estimations of the hæmoglobin cont of capillary blood, the blood-volumes calculated fr these different angles were close—3 9, 4 0, 3 8, 4 1 lit respectively Fallacy is well shown by case 16 where autopsy two days later made it clear that he was activ bleeding at the time of investigation Continuance bleeding renders the calculation inaccurate, biasing th result towards underestimate of blood-loss in direct p portion to the amount of bleeding From the clinical asp there can be no doubt that continuance of bleeding is t commonest cause of failure to affect a rise in blood pres despite adequate transfusion Table II sets out th calculated blood-loss, the total and protein fluid restor to the circulation, and the effect of this on the blood pressure The results show that when the calculat blood-loss is restored to the extent of 50% or more t effect on the blood-pressure is usually satisfactory The hæmatological results therefore confirm the accept clinical belief that transfusion should continue until blood-pressure has been satisfactorily restored But th also provide a valuable check on clinical impression Fo example, case 16 shows that when the calculated blood loss is disproportionately small in relation to the amount of fluid necessary to restore blood-pressure, continuou unrevealed bleeding should be suspected There are also other, perhaps uncommon, causes of a sustained low blood-pressure in a wounded man besides reduced blood volume The simple hæmatological check combined with good clinical judgment can prevent such cases from having a gross excess of fluid transfused in an effort to restore blood-pressure, so avoiding the danger of pulmonary œdema

Table II analyses the fluid administered in terms of it protein content—that is, of that portion of the fluid which will remain in the circulation, in contrast to the crystalloid portions which are invariably excreted fairly quickly The results show the effect on blood pressure up to the end of the resuscitation period The importance of maintaining the good effect during the operation period has already been stressed For this permanent result only the protein fraction can be considered effective

TABLE II—HÆMATOLOGICAL FINDINGS AND RELATION OF CALCULATED BLOOD-LOSS AND INTRAVENOUS FLUID REPLACEMENT TO BLOOD PRESSURE BEFORE AND AFTER RESUSCITATIVE (BUT NOT OPERATIVE) TREATMENT

• Probably bleeding Un = Unrecordable N R = Not recorde

Hence it is essential that the transfused protein fractio should be not less than 50% of the fluid lost and preferabl more, bearing in mind that with Army Blood-transfusio Service plasma of every 7 pints transfused 2 are lost crystalloids The experimental results of Maglader Solandt and Best (1940) showed that a protein replace ment of at least 40% was required when treating hæmo rhagic shock with serum rly according to convenience The first or loading" se is ¼ g higher than the average dose for a child cept an infant under six months) and ½ g higher for adult In all severe cases especially those in coma se who cannot or will not swallow, and those who are miting the drug should be given intravenously for e or two doses and thereafter by mouth or stomach-be The 5% sodium solution may be given intra-scularly if intravenous injection is impracticable trathecal injection should never be given, the solution dangerously irritating A dose of 20 c cm (1 g) of e sodium solution given intravenously is usually fficient for an adult, 40 c cm may be given in a very vere case For a young child or infant 10 c cm (½ g) ffices The external jugular vein is a convenient site r injection in infants

Such dosage of sulphathiazole has so far proved to be most entirely non-toxic, and this is the great advantage the drug over sulphapyridine Nausea vomiting d consequently dehydration were rare · only 7 cases mited twice or more A single intravenous injection sodium sulphathiazole seemed to stop the vomiting rikingly in 2 children in another case an enema had e desired effect There was neither mental depression r disorientation such as are common with sulphapyri-ine, and cyanosis was absent or slight Drug rash, rug fever, erythema nodosum and hæmaturia (all of hich are said to be fairly common with sulphathiazole) ere not encountered in this series possibly owing to he relatively short periods of treatment Slight leuco-enia occurred in 1 case, a boy aged three years who eceived 24 g of sulphathiazole in seven days, his white ells numbered 4600, with 70% polymorphs on the eventh day of treatment, the drug was stopped imme-iately and the next day the white cells were 5500 and hereafter steadily increased This relative non-toxicity f sulphathiazole justifies the high initial dosage of 3 g aily for infants and 9 g daily for adults I believe that losage of any of the three sulphonamide drugs should ever be lower than this in meningitis

Sulphapyridine is still often given in what might be alled the "pneumonia dosage"—6 g daily (after the two preliminary "loading doses") in adults, and about 1 g daily in infants I quote 2 examples which serve to indicate that these amounts are inadequate and therefore may be dangerous in meningitis

CASE 1—A woman of 54 was admitted to a general hospital semi-comatose, with petechial rash on body and limbs, neck rigidity, pharyngitis and bronchitis The C S F was purulent and contained meningococci She was treated with 20 c cm Soluseptasine intravenously, followed by sulphapyridine 6 g daily for two and a half days, when she was transferred to the Park Hospital She was still semi comatose, with neck rigidity and a petechial rash, the C S F contained over 5000 cells per c.mm and still showed meningococci in films, although they did not grow on culture She was put on sulphathiazole 9 g daily In 48 hours the C S.F contained 335 cells per c mm (mononuclears 60%) and no organisms, and she was rational and comparatively well During ten days she received 15 g of sulphapyridine and 43 g of sulphathia-zole Eleven days after the drug was stopped she relapsed, meningeal signs reappeared and the C S.F was again turbid, with over 1000 cells per c.mm but no organisms demonstrated She was put on a second course of sulphathiazole, beginning with 12 g in the first twenty four hours, followed by 9 g in the next three days, the dosage was then gradually reduced During the relapse she had 64 g sulphathiazole in eight and a half days, at the end of which period blood counts were normal She made a complete and rapid recovery from the relapse

This was the only relapse in the whole series and I consider it to be associated with the low dosage (6 g) of sulphapyridine in the first two and a half days

CASE 2—A boy aged 10 months was admitted to a general hospital with the diagnosis of pneumonia Sulphapyridine ¼ g was given thrice daily for two and a half days Increasing neck rigidity, irritability and tense fontanelle, lumbar punc-ture then yielded a turbid C S F still containing meningococci He was transferred to the Park Hospital where 1 g of sulpha-thiazole was given as a loading dose, followed by 3 g daily for three days; the dose was then gradually reduced Within three days all neck rigidity had disappeared and recovery was rapid He was discharged after seventeen days

I do not know why infants and young children require an amount of the drug two or three times as high in proportion to body-weight as that which is appropriate for adults I do know, however that they tolerate it and that any less amount may be dangerous These were the only 2 cases in the series in which meningococci were demonstrated as long as two and a half days after chemotherapy began and I think that the dosage of sulphapyridine was dangerously low

COMPLICATIONS

Paresis of the right sixth cranial nerve developed in 5 cases of the left in 1 of both sixth nerves in 1 and of the right seventh in 2 These pareses all cleared up in periods ranging from a few days to three months The serious lesion of the eighth nerve which results in absolute deafness is noted under 'sequelæ" Arthritis or bursitis occurred in 8 cases involving variously the fingers wrist elbow shoulder and knee-joints The synovial fluid was often turbid but the joints cleared up in a few weeks or less Glycosuria was present for two days after admission in one case, a woman of fifty, and there was no ketosis Shallow sprawling vesicles and ulcers in the purpuric areas of the rash were noted in 3 cases and were probably meningococcal in origin No organisms were isolated from these ulcers or from joint exudates probably owing to the effect of the drug In one case there was a relapse of the meningitis

There were only 2 deaths in the whole series The first was a fulminating case in a man of forty-five who was found in absolute coma and died within twenty-one hours of admission He had a total of 6½ g of sulphathiazole The other patient (case 3) died six hours after admission—before sulphathiazole could be effective

CASE 3—A soldier aged 19 was admitted on the second day of disease complaining of intense headache and pains in limbs There was a profuse petechial rash on trunk and limbs, considerable neck rigidity and some head retraction He was restless and irritable when disturbed, and drowsy, but not comatose The C S F was slightly turbid, under pressure and contained meningococci He was difficult to manage at lumbar puncture and was therefore given morphine gr ⅓ and hyoscine gr $\frac{1}{100}$ hypodermically Four hours later he was still rather restless, the pulse was good, respirations not shallow, but the pupils were contracted, he was swallowing drinks quite well Two hours later he was found by the nurse pulseless and moribund and with pupils widely dilated He died five minutes later, six hours after admission. Treatment was by sulphathiazole 2 g by mouth on admission and 1½ g four hours later, a total of 3½ g At autopsy there was moderate congestion of the meningeal vessels and some sero fibrinous exudate about the optic chiasma and in the sulci

This death was unexpected He was a healthy young man and with only a moderately severe attack of meningitis which we had expected to cure rapidly by chemotherapy An experience of two or three similar cases suggests that the morphine and hyoscine was an indirect cause of this death although there was no actual evidence of morphine poisoning In acute meningitis hypodermic morphine is best restricted to gr ⅙ at any one dose

SEQUELÆ

The *only* sequela of practical importance was deafness This is a nerve deafness, often absolute, permanent and bilateral and it is now a serious public-health problem and calls for special measures of aftercare In 2 cases the deafness was fortunately partial and cleared up in a few days No less than 5 patients developed absolute or nearly absolute deafness in 4 it was bilateral and 1 unilateral The ages were 3, 4 6 32 and 54 years respectively In at least 2 cases a vestibular lesion causing difficulty in balancing was present in addition, but this cleared up or was compensated almost completely after several weeks The deafness in 2 cases was noted on the day before admission to hospital, and in the other 3 cases, all young children, it was probably present on admission In only one case was any sulphonamide drug given and then only g ½ before signs of deafness appeared Deafness in meningitis thus appears in the early acute stage, is not due to the drug and was apparently cured in only 2 cases out of 7 The apparent

SULPHATHIAZOLE IN CEREBROSPINAL FEVER

By H STANLEY BANKS, M D Glasg, D P H
MEDICAL SUPERINTENDENT, PARK HOSPITAL, L C C

INTEREST in sulphathiazole (2 *p* amino benzene sulphonamide thiazole), M & B 760, Thiazamide or Ciba 3714, since January, 1940, has been chiefly focused on its action in staphylococcal and more recently in pneumococcal infections Gsell (1940) reported favourably on the treatment of pneumococcal, gonococcal, coliform and meningococcal infections with this drug, and described 7 cases of cerebrospinal fever, all of which recovered Since then, apart from a brief reference of my own to 15 cases (Banks 1940a), I have been able to trace only three articles on the use of sulphathiazole in cerebrospinal fever, all in Hungarian journals, and have been unable to obtain translations In America there is a disposition to view with disfavour the employment of sulphathiazole in meningitis because it achieves only a low concentration in the cerebrospinal fluid According to Rammelkamp (1940) "sulphathiazole diffuses irregularly into the cerebrospinal fluid and therefore has not been used in meningitis" Carey (1940) goes so far as to state that "it should not be used in meningitis, as its concentration in the spinal fluid reaches only from 10 to 30% of that in other body fluids" I hope to show, however, that this conclusion is contradicted, at least for meningococcal meningitis, by the success obtained in practice, although I admit that Carey's premises are substantially correct

Sulphathiazole treatment was adopted at the Park Hospital in May, 1940, and used exclusively during the post-epidemic period, May 15–Dec 27, 1940 The cases, on the whole, were intermediate in severity between those of the epidemic period (January–May, 1940) and those of the two previous seasons of sporadic incidence, 1937–38 and 1938–39, when other sulphonamide drugs were used Of the 96 cases treated with sulphathiazole 17 were classified as mild 50 as moderate, 26 as severe and 3 as very severe Exactly a third (32 cases) had petechial or purpuric rashes It was difficult to make an accurate clinical assessment of severity, owing to the exceedingly rapid improvement effected even in the most severe cases by sulphathiazole, especially by an intravenous injection For the same reason the meningococcus could not be demonstrated in a considerable proportion of cases Many of the patients had had one or more doses of sulphapyridine in the general hospital from which they were transferred Thus, though all were typical clinical cases and had turbid or purulent cerebrospinal fluid the meningococcus was seen or grown in 66 only, typing in 25 cases showed 17 of group I, 5 group II and 3 inagglutinable Of the whole series 7 had had sulphapyridine treatment before admission for thirty-six hours or more, 4 of these were judged to be recovering on admission and were accordingly excluded and classed with the sulphapyridine series The remaining 3 cases had a dosage of sulphapyridine which is not unusually given but which I am now convinced is dangerously low—e g, 6 g daily for an adult, or 1 g daily for an infant of 10 months Of these cases 2 had meningococci in the C S F after two and a half days of treatment, a thing which never occurred after sulphathiazole in standard dosage, and the third case had flakes of exudate still coming away through the lumbar puncture needle All 3 rapidly recovered on sulphathiazole and were therefore allocated to the sulphathiazole series

TABLE I—RESULTS OF CHEMOTHERAPY IN PREVIOUS SERIES

Age group (years)	1937–38* (sporadic)		1938–39† (sporadic)		Jan –May 1940† (epidemic)	
	Cases	Deaths	Cases	Deaths	Cases	Deaths

Results of treatment in three series of cases treated in this hospital since chemotherapy was introduced are given in table I (see Banks 1938, 1939, 1940b) The age-grouping is somewhat similar in both tables except that, in the sulphathiazole series (table II) the proportion of infants is somewhat lower and of patients over forty somewhat higher In 1937–38 treatment was by serum and sulphanilamide In 1938–39 and in January–May, 1940, treatment was by sulphanilamide or sulphapyridine or both drugs combined Results in the present series of cases (table II) treated with sulphathiazole alone, or with a few preliminary doses of sulphapyridine, compare favourably with those of all three previous series The case-fatality rate of 2 1% in the sulphathiazole series is actually the lowest yet obtained in this hospital In assessing these figures some regard should be had to the relative mildness of post-epidemic as compared with epidemic cases and also to the fact that our technique has improved as experience of chemotherapy has matured Sulphathiazole has not yet been tested under epidemic conditions Nevertheless, it has already given satisfactory results in some very severe cases, such as cases 4 and 5 below The single case in which it failed was a fulminating one with early and absolute coma similar to those which so often proved fatal during the epidemic period, when sulphapyridine was the drug employed Taking all things into consideration, I regard sulphathiazole as the most satisfactory drug which I have so far used in meningococcal meningitis

DOSAGE AND TOXICITY

I followed the dosage scheme which I originally adopted for sulphanilamide and later for sulphapyridine in the treatment of meningococcal meningitis

Age group	Under 2	2–5	5–10	10–15	Over 15
Daily dose (g)	3	4½	6	7½	9

This scheme was maintained for an initial period of two to three days according to severity, then two-thirds of the dose was given for two days and finally one-third for a further two days The period of administration is six to seven days and the total amount of the drug given is 10–50 g for an adult The drug is given four-hourly during the initial period and thereafter four- or six urly according to convenience. The first or "loading" se is ¼ g higher than the average dose for a child cept an infant under six months) and ½ g higher for adult In all severe cases, especially those in coma, ose who cannot or will not swallow, and those who are miting, the drug should be given intravenously for e or two doses and thereafter by mouth or stomach-be The 5% sodium solution may be given intra-uscularly if intravenous injection is impracticable trathecal injection should never be given, the solution dangerously irritating A dose of 20 c cm (1 g) of e sodium solution given intravenously is usually fficient for an adult, 40 c cm may be given in a very vere case For a young child or infant 10 c cm (½ g) ffices The external jugular vein is a convenient site r injection in infants

Such dosage of sulphathiazole has so far proved to be most entirely non-toxic, and this is the great advantage the drug over sulphapyridine Nausea, vomiting nd consequently dehydration were rare, only 7 cases omited twice or more A single intravenous injection f sodium sulphathiazole seemed to stop the vomiting rikingly in 2 children, in another case an enema had ne desired effect There was neither mental depression or disorientation such as are common with sulphapyri-ine, and cyanosis was absent or slight Drug rash, rug fever, erythema nodosum and hæmaturia (all of hich are said to be fairly common with sulphathiazole) ere not encountered in this series, possibly owing to he relatively short periods of treatment Slight leuco-enia occurred in 1 case, a boy aged three years who eceived 24 g of sulphathiazole in seven days, his white ells numbered 4600, with 70% polymorphs on the eventh day of treatment, the drug was stopped imme-hately and the next day the white cells were 5500 and hereafter steadily increased This relative non-toxicity of sulphathiazole justifies the high initial dosage of 3 g laily for infants and 9 g daily for adults I believe that losage of any of the three sulphonamide drugs should never be lower than this in meningitis

Sulphapyridine is still often given in what might be called the "pneumonia dosage"—6 g daily (after the two preliminary "loading doses") in adults, and about 1 g daily in infants I quote 2 examples which serve to indicate that these amounts are inadequate and therefore may be dangerous in meningitis

Case 1—A woman of 54 was admitted to a general hospital semi comatose, with petechial rash on body and limbs, neck rigidity, pharyngitis and bronchitis The C S F was purulent and contained meningococci She was treated with 20 c cm Soluseptasine intravenously, followed by sulphapyridine 6 g daily for two and a half days, when she was transferred to the Park Hospital She was still semi comatose, with neck rigidity and a petechial rash, the C S F contained over 5000 cells per c mm and still showed meningococci in films, although they did not grow on culture She was put on sulphathiazole 9 g daily In 48 hours the C S F contained 355 cells per c mm (mononuclears 60%) and no organisms, and she was rational and comparatively well During ten days she received 15 g of sulphapyridine and 43 g of sulphathia-zole Eleven days after the drug was stopped she relapsed, meningeal signs reappeared and the C S F was again turbid, with over 1000 cells per c mm but no organisms demonstrated She was put on a second course of sulphathiazole, beginning with 12 g in the first twenty-four hours, followed by 9 g in the next three days, the dosage was then gradually reduced During the relapse she had 64 g sulphathiazole in eight and a half days, at the end of which period blood counts were normal She made a complete and rapid recovery from the relapse

This was the only relapse in the whole series and I consider it to be associated with the low dosage (6 g) of sulphapyridine in the first two and a half days

Case 2—A boy aged 10 months was admitted to a general hospital with the diagnosis of pneumonia Sulphapyridine ¼ g was given thrice daily for two and a half days Increasing neck rigidity, irritability and tense fontanelle, lumbar puncture then yielded a turbid C S F still containing meningococci He was transferred to the Park Hospital where 1 g of sulpha thiazole was given as a loading dose, followed by 3 g daily for three days, the dose was then gradually reduced Within three days all neck rigidity had disappeared and recovery was rapid He was discharged after seventeen days

I do not know why infants and young children require an amount of the drug two or three times as high in proportion to body-weight as that which is appropriate for adults I do know, however, that they tolerate it and that any less amount may be dangerous These were the only 2 cases in the series in which meningococci were demonstrated as long as two and a half days after chemotherapy began, and I think that the dosage of sulphapyridine was dangerously low

COMPLICATIONS

Paresis of the right sixth cranial nerve developed in 5 cases, of the left in 1, of both sixth nerves in 1 and of the right seventh in 2 These pareses all cleared up in periods ranging from a few days to three months The serious lesion of the eighth nerve which results in absolute deafness is noted under "sequelæ" Arthritis or bursitis occurred in 8 cases, involving variously the fingers wrist, elbow, shoulder and knee-joints The synovial fluid was often turbid but the joints cleared up in a few weeks or less Glycosuria was present for two days after admission in one case, a woman of fifty, and there was no ketosis Shallow sprawling vesicles and ulcers in the purpuric areas of the rash were noted in 3 cases, and were probably meningococcal in origin No organisms were isolated from these ulcers or from joint exudates, probably owing to the effect of the drug In one case there was a relapse of the meningitis

There were only 2 deaths in the whole series The first was a fulminating case in a man of forty-five who was found in absolute coma and died within twenty-one hours of admission He had a total of 6½ g of sulphathiazole The other patient (case 3) died six hours after admission—before sulphathiazole could be effective

Case 3—A soldier aged 19 was admitted on the second day of disease complaining of intense headache and pains in limbs There was a profuse petechial rash on trunk and limbs, considerable neck rigidity and some head retraction He was restless and irritable when disturbed, and drowsy, but not comatose The C S F was slightly turbid, under pressure and contained meningococci He was difficult to manage at lumbar puncture and was therefore given morphine gr ⅓ and hyoscine gr $\frac{1}{100}$ hypodermically Four hours later he was still rather restless, the pulse was good, respirations *not* shallow, but the pupils were contracted, he was swallowing drinks quite well Two hours later he was found by the nurse pulseless and moribund and with pupils widely dilated He died five minutes later, six hours after admission Treatment was by sulphathiazole 2 g by mouth on admission and 1½ g four hours later, a total of 3½ g At autopsy there was moderate congestion of the meningeal vessels and some sero fibrinous exudate about the optic chiasma and in the sulci

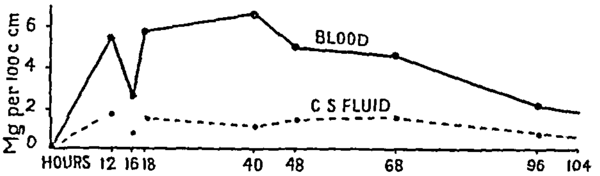
This death was unexpected He was a healthy young man and with only a moderately severe attack of meningitis which we had expected to cure rapidly by chemotherapy An experience of two or three similar cases suggests that the morphine and hyoscine was an indirect cause of this death although there was no actual evidence of morphine poisoning In acute meningitis hypodermic morphine is best restricted to gr ⅙ at any one dose

SEQUELÆ

The only sequela of practical importance was deafness This is a nerve deafness, often absolute, permanent and bilateral, and it is now a serious public-health problem and calls for special measures of aftercare In 2 cases the deafness was fortunately partial and cleared up in a few days No less than 5 patients developed absolute or nearly absolute deafness, in 4 it was bilateral and 1 unilateral The ages were 3, 4, 6, 32 and 54 years respectively In at least 2 cases a vestibular lesion causing difficulty in balancing was present in addition, but this cleared up or was compensated almost completely after several weeks The deafness in 2 cases was noted on the day before admission to hospital, and in the other 3 cases, all young children, it was probably present on admission In only one case was any sulphonamide drug given, and then only g ½, before signs of deafness appeared Deafness in meningitis thus appears in the early acute stage, is not due to the drug and was apparently cured in only 2 cases out of 7 The apparent increase in deafness following cerebrospinal fever in the last few years is probably a result of the high proportion of recoveries now being obtained by chemotherapy A follow-up scheme should now be instituted to ensure for the affected children facilities for special education and training, and for the adults training in lip-reading

CONCENTRATION OF SULPHATHIAZOLE IN BLOOD AND C S F

It is apparent from these results that sulphathiazole is an effective drug in cerebrospinal fever, yet the concentration of the drug in the C S F is much lower for a given dose than that of sulphanilamide and somewhat lower than that of sulphapyridine Even in the blood-stream, concentrations higher than 6 or 7 mg per 100 c cm are rarely obtained owing to the rapidity of absorption and excretion The concentration curve in the C S F does not follow that in the blood, but flattens out as the blood-concentration rises, so that it seldom rises above 1 5 mg per 100 c cm Only in one patient, a lad of eighteen, was the concentration in the C S F as high as 3 1 mg When the concentration in the blood is at its highest the value in the C S F is only about 15% of that in the blood In the early and late stages of the period of administration, however, the concentration in the C S F may reach as high as 40% of that in the blood



The graph given here is a composite one representing a simultaneous blood and C S F estimation in 8 different patients of widely different ages and at different times after the beginning of treatment Care has been taken to eliminate any cases in which the previous administration of sulphapyridine might invalidate the result The ages of the 8 patients represented in the successive estimations were 15, 50, 15, 54, 8, 3, 19 and 35

Table III gives the concentrations in the C S F of 15 other cases in different age-groups All cases represented in the graph and table were treated according to the standard dosage scheme, with its much higher dosage in proportion to body-weight at the younger ages Nevertheless this factor appears to have had little influence on the concentrations in the C S F In the 15 cases the average concentrations in the C S F after the beginning of treatment were at 18 hours 0 8 mg , at 36–40 hours 1 05 mg , at 48–60 hours 1 29 mg , at 96 hours or later 0 5 mg per 100 c cm

TABLE III—CONCENTRATION OF SULPHATHIAZOLE IN C S F IN MG PER 100 C CM

Age group (years)	Cases	Hours after treatment began—			
		18	36–40	48–60	96 +
1–3	4	0 5 1 0	—	1 6	0 6 0 5
6–7	2	—	—	—	0 6 0 3
17–19	2	—	0 83	—	0 5
21	1	—	2 0	1 7	tr
28–41	6	0 9	0 7 0 9 0 85	1 1 0 78	—
Average 15 cases		0 8	1 05	1 29	0 5

Every one of the cases represented in the graph and table recovered rapidly Accordingly it appears that relatively low concentrations in the C S F, varying from 0 8 to 1 3 mg per 100 c cm in the first three days, are effective It would be unwise, however, to use these data to justify any reduction in the dosage during the initial period

COURSE OF THE DISEASE WITH SULPHATHIAZOLE

Except for 2 or 3 very severe cases recovery was ra Patients were comfortable and rational within twe- four hours, and children were often found sitting up bed within this period After the first lumbar punct in many cases the C S F was not examined again, experience has shown lumbar puncture to be unnece for treatment, except in rare instances where slow p or respirations or great restlessness and headache indic high pressure in the fluid However, 46 specimen C S F were examined within forty-eight hours after t diagnostic lumbar puncture had shown meningococci t be present Of these, 5 specimens were taken with twelve hours, all of which were free from organism 23 were taken from twelve to twenty-four hours af diagnostic puncture, and of these only 6 showed meningococci in films, with no growth on culture, 11 specime were taken between thirty-six and forty-eight hours aft diagnostic puncture and all except one were not only fr from organisms but showed a great reduction in the cel count and a considerable percentage of mononuclears already present This suggests that bacteriostasis w effected within twenty-four hours, that, in the gre majority, phagocytosis of free organisms had also tak place within this period, and that within forty eigh hours the process of absorption of the exudate was we advanced

The following are examples of very severe cases successfully treated with sulphathiazole

CASE 4 —A male infant of four months had been vaccinat a fortnight before admission and had been nightly to a publ shelter Severe illness began forty eight hours befo admission On admission, on Dec 3, 1940, the infant was suffering from both severe meningococcal meningitis and acute pneumonia He was cyanosed, the alæ nasi were moving freely and respirations were rapid and grunting Th temperature was 96° F on admission (a collapse temperature which later rose to 101° F), pulse rate about 160, almo uncountable, and respirations 70 Sticky râles all over che and over the right lower lobe dullness to percussion and coar moist râles The skin showed a few petechial spots on trunk and thighs The neck was rigid Lumbar puncture produced a few c cm of creamy purulent fluid, containing 53,8 cells per c mm and meningococci in films and culture (group I) His condition was desperate and he was given at once 10 c cm (0 5 g) of the solution of sodium sulphathiaz into the jugular vein and put into an oxygen tent, whence h was removed for feeding every two hours One tablet of th drug (0 5 g) was given by mouth four hourly for four day and then gradually reduced Improvement was very gradual He remained in the oxygen tent for seven days His temperature settled to normal in ten days Pulse rate remained abo 160 and respirations 70 for four days and then gradually slowed His chest was clear of gross signs within four day but some bronchitis remained for two weeks On Dec 1 a blood count showed secondary anæmia, Hb 62%, and a leucocytosis of 15,100, with 55% polymorphs His an was treated and he was soon quite well It was not po to determine the infecting organism of the pneumonia Sulphathiazole was evidently effective, however, against both meningeal and pulmonary infections in an infant who condition on admission was well nigh desperate

CASE 5 —A girl of 15 had about twelve hours' malaise before the onset of intense headache and vomiting Four hours later she was delirious and comatose, the coma rapidly becoming absolute She was admitted to a general hospital at one of the most intense periods of the bombing of London and received at once 1 g of sulphapyridine intramuscularly, but received no further drug treatment until she was tran- ferred to Park Hospital twenty seven hours later, on Sept 2 She was then in absolute coma and totally unable to swallow, mouth and tongue were dry and dirty , skin dry , dehydrated neck rigid but otherwise general flaccidity Abdominal reflexes absent Left sixth cranial nerve paresis The C S F was very purulent and contained meningococci of group I in films and culture Immediate treatment was 2 g sulphathiazole (40 c cm of 5% sodium solution) intravenously followed in two hours by 1 5 g by mouth and then 1 5 g four hourly Fluids and drug were given freely by stomach tube and continuous drip rectal saline was also given Next day she was still in absolute coma and unable to swallow, moist sounds at the bases of lungs , C S F contained 17,00 ls but no organisms Coma still absolute on Sept 27, she is unable to swallow but was now beginning to show a ght response to stimuli, loose cough present, fluids and ug had been given by tube for forty eight hours Next y there was definite improvement, she did not speak but is able to swallow, left and right sixth nerve paresis, more vere on the left, blurring of the margins of optic discs and ght papillœdema On Oct 3 C S F contained 24 cells per mm and no organisms Next day papillœdema had dis ppeared Thereafter her progress was rapid She was scharged well except for left internal squint on Nov 4

Convalescence was so rapid that almost all patients xcept those with arthritis or deafness were discharged ithin three weeks of admission, some in just over two eeks On discharge it was noted that the tendon flexes, particularly knee- and ankle-jerks were as a rule ill exaggerated and the C S F might contain up to 0 or 15 lymphocytes per c mm There were no clinical isabilities, except in the complicated cases These ccasionally showed slight residual paresis of the sixth nd seventh nerves some joint stiffness in certain cases f arthritis, and the deafness already referred to

The management of cases on sulphathiazole treatment , relatively easy owing to the comparative absence of oxic effects Vomiting produced by sulphapyridine was enerally checked when the drug was changed to sulphahiazole If vomiting does occur the tablets should be epeated and if it persists the sodium solution should be njected intravenously in place of treatment by mouth One or more intravenous injections should also be given o every severe case

PROGNOSIS

Tables I and II show that the age-groups with the worst rognosis are still under a year and over forty, though his feature is not nearly so clear-cut as in the days of erum therapy When chemotherapy is adequately pplied the determining factor in prognosis appears to e the fulminating type with or without adrenal æmorrhage This may occur at all ages but is probably ost frequent in infancy, as was actually seen during he 1940 epidemic In elderly subjects a secondary actor of some importance in prognosis is intercurrent rganic disease The prognosis in elderly subjects, however is now immensely improved Of 29 cases over orty treated during 1940 there were only 2 deaths, one fulminating case and the other due to hypostatic neumonia in a man aged seventy-four

SUMMARY

In the post-epidemic period of 1940, 96 consecutive cases of cerebrospinal fever were treated with 2 deaths In 52 cases sulphathiazole was used after one or more preliminary doses of sulphapyridine, and in 44 cases sulphathiazole was used alone The fatality-rate of cases treated mainly or wholly with sulphathiazole was 2 1%, which compares favourably with previous series treated with serum and sulphanilamide and with sulphanilamide or sulphapyridine alone or combined

Sulphathiazole, though not yet tested in epidemic conditions, has rapidly cured some very acute cases The evidence so far suggests that it is at least equal in potency to sulphapyridine in meningococcal disease There is evidence that, with adequate dosage, bacteriostasis is complete and phagocytosis advanced within twelve to twenty-four hours

Concentration in the C S F varies from about 15 to 40% of that in the blood, and rarely is greater than 1 5 mg per 100 c cm even on high dosage

The comparative rarity of nausea vomiting and dehydration, and the absence of depression and mental confusion, make the treatment with sulphathiazole more pleasant, and the management of the case easier than with sulphapyridine Other toxic effects are also rare High dosage is well tolerated

One or two intravenous injections of the 5% sodium solution are recommended in all severe cases and where vomiting persists

I have to thank Messrs May and Baker for supplies of tablets of Thiazamide and of ampoules of the 5% sodium solution of M & B 760, and Messrs Ciba for supplies of tablets of Ciba 3714 and relevant foreign literature Thanks are also due to the medical superintendents of the L C C general hospitals for their cooperation in transferring cases promptly, and to many members of my medical and nursing staff for their assistance The pathological and biochemical work was done at the Southern Group Laboratory by Dr J E McCartney and Dr E M Young The medical officer of health of the London County Council has kindly granted permission for the publication of this paper, for which the council accepts no responsibility

(*From an E M S neurological unit*)

SINCE the beginning of the war over 1500 cases of neurosis or psychosis in members of the armed forces have been treated in this hospital and the more important conclusions drawn from this experience may be of use to those dealing with similar problems[1]

The cases have ranged from the extremely chronic to the most acute In the early months of the war they consisted largely of men who, had all the facts been known, would never have been regarded as fit for military service—mental defectives, epileptics and the chronically anxious or hysterical—who had broken down at once under the stress of active-service conditions and removal from home They included a large number of the constitutionally abnormal, but most of them were *not* openly concerned to make the most of their symptoms With the onset of violent fighting and at the evacuation from Dunkirk different types of case began to appear—acute anxiety or exhaustion syndromes in men of comparatively normal personality, who had not broken down until placed under considerable strain In these the prospects of treatment were good, and most of them could be returned to the Army in capacities where the strain was not likely to reach the same level again Since then cases of a third type have appeared in men who have broken down under aerial bombardment in this country The strain experienced has never reached the intensity endured in the Dunkirk episode, and it is not surprising to find that these patients are of feebler stamina, and that the constitutional element was once again well to the fore What has been surprising, however is that hysterical mechanisms have been much more superficial in many of them, and in a few have almost reached the level of open malingering, to others even the most cautious psychiatrist might be tempted to apply the term "scrimshanker" It may be that these men breaking down at a later stage in the war, and being less obviously unfit for service, feel that they must bolster up their illness with adventitious aid, or rather, perhaps evade further unpleasant necessity by refusing to consider the possibility of natural recovery

THE AIM OF TREATMENT

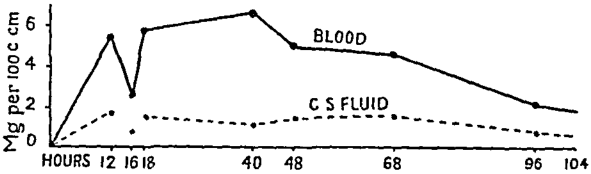
With the neurotic war casualty, to a much greater extent than with the private patient of peace-time, treatment has to be limited by practical possibilities We hold, contrary to some that it is impossible by psychotherapy to reconstitute the make-up of the personality, that the neurotic cannot be freed of his neurotic tendencies In any case, radical psychotherapy is out of the question in war conditions, if only because of the time required increase in deafness following cerebrospinal fever in the last few years is probably a result of the high proportion of recoveries now being obtained by chemotherapy A follow-up scheme should now be instituted to ensure for the affected children facilities for special education and training, and for the adults training in lip-reading

---

[1] Apart from a proportion of very acute cases our material closely resembles both diagnostically and prognostically the Naval material analysed by Desmond Curran and W P Mallinson (*Lancet* 1940, 2, 738)

CONCENTRATION OF SULPHATHIAZOLE IN BLOOD AND C S F

It is apparent from these results that sulphathiazole is an effective drug in cerebrospinal fever, yet the concentration of the drug in the C S F is much lower for a given dose than that of sulphanilamide and somewhat lower than that of sulphapyridine Even in the blood-stream, concentrations higher than 6 or 7 mg per 100 c cm are rarely obtained owing to the rapidity of absorption and excretion The concentration curve in the C S F does not follow that in the blood, but flattens out as the blood-concentration rises, so that it seldom rises above 1 5 mg per 100 c cm Only in one patient, a lad of eighteen, was the concentration in the C S F as high as 3 1 mg When the concentration in the blood is at its highest the value in the C S F is only about 15% of that in the blood In the early and late stages of the period of administration, however, the concentration in the C S F may reach as high as 40% of that in the blood



The graph given here is a composite one representing a simultaneous blood and C S F estimation in 8 different patients of widely different ages and at different times after the beginning of treatment Care has been taken to eliminate any cases in which the previous administration of sulphapyridine might invalidate the result The ages of the 8 patients represented in the successive estimations were 15, 50, 15, 54, 8, 3, 19 and 35

Table III gives the concentrations in the C S F of 15 other cases in different age-groups All cases represented in the graph and table were treated according to the standard dosage scheme, with its much higher dosage in proportion to body-weight at the younger ages Nevertheless this factor appears to have had little influence on the concentrations in the C S F In the 15 cases the average concentrations in the C S F after the beginning of treatment were at 18 hours 0 8 mg , at 36–40 hours 1 05 mg , at 48–60 hours 1 29 mg , at 96 hours or later 0 5 mg per 100 c cm

TABLE III—CONCENTRATION OF SULPHATHIAZOLE IN C S F IN MG PER 100 C CM

Age group (years)	Cases	Hours after treatment began—			
		18	36–40	48–60	96 +
1–3	4	0 5 1 0	—	1 6	0 6 0 5
6–7	2	—	—	—	0 6 0 3
17–19	2	—	0 83	—	0 5
21	1	—	2 0	1 7	tr
28–41	6	0 9	0 7 0 9 0 85	1 1 0 78	—
Average 15 cases		0 8	1 05	1 29	0 5

Every one of the cases represented in the graph and table recovered rapidly Accordingly it appears that relatively low concentrations in the C S F , varying from 0 8 to 1 3 mg per 100 c cm in the first three days, are effective It would be unwise, however, to use these data to justify any reduction in the dosage during the initial period

COURSE OF THE DISEASE WITH SULPHATHIAZOLE

Except for 2 or 3 very severe cases recovery was ra Patients were comfortable and rational within twe- four hours, and children were often found sitting up bed within this period After the first lumbar punct in many cases the C S F was not examined again, experience has shown lumbar puncture to be unnece for treatment, except in rare instances where slow p or respirations or great restlessness and headache indic high pressure in the fluid However, 16 specimens C S F were examined within forty-eight hours after diagnostic lumbar puncture had shown meningococci be present Of these, 5 specimens were taken with twelve hours, all of which were free from organ 23 were taken from twelve to twenty-four hours a diagnostic puncture, and of these only 6 showed menin cocci in films, with no growth on culture , 11 specim were taken between thirty-six and forty-eight hours aft diagnostic puncture and all except one were not only fr from organisms but showed a great reduction in the c count and a considerable percentage of mononucle already present This suggests that bacteriostasis w effected within twenty-four hours , that, in the gre majority, phagocytosis of free organisms had also tak place within this period , and that within forty-eig hours the process of absorption of the exudate was w advanced

The following are examples of very severe cases succe fully treated with sulphathiazole

Case 4 —A male infant of four months had been vaccina a fortnight before admission and had been nightly to a pu shelter Severe illness began forty eight hours b admission On admission, on Dec 3, 1940, the infant w suffering from both severe meningococcal meningitis a acute pneumonia He was cyanosed, the alæ nasi were m ing freely and respirations were rapid and grunting Th temperature was 96° F on admission (a collapse temperatu which later rose to 101° F), pulse rate about 160, alm uncountable, and respirations 70 Sticky râles all over ch and over the right lower lobe dullness to percussion and coar moist râles The skin showed a few petechial spots on tru and thighs The neck was rigid Lumbar puncture p duced a few c cm of creamy purulent fluid, containing 53, cells per c mm and meningococci in films and culture (grou I) His condition was desperate and he was given at onc 10 c cm (0 5 g) of the solution of sodium sulphathia into the jugular vein and put into an oxygen tent, whence h was removed for feeding every two hours One tablet of th drug (0 5 g) was given by mouth four hourly for four da and then gradually reduced Improvement was very gradua He remained in the oxygen tent for seven days His tempe ture settled to normal in ten days Pulse rate remained ab 160 and respirations 70 for four days and then graduall slowed His chest was clear of gross signs within four da but some bronchitis remained for two weeks On Dec 1 a blood count showed secondary anæmia, Hb 62%, and a leucocytosis of 15,100, with 55% polymorphs His anæm was treated and he was soon quite well It was not possib to determine the infecting organism of the pneumonia Sulphathiazole was evidently effective, however, against both meningeal and pulmonary infections in an infant who condition on admission was well nigh desperate

Case 5 —A girl of 15 had about twelve hours' malaise before the onset of intense headache and vomiting Four hours later she was delirious and comatose, the coma rapidly becoming absolute She was admitted to a general hospital at one of the most intense periods of the bombing of London and received at once 1 g of sulphapyridine intramuscularly, but received no further drug treatment until she was tran ferred to Park Hospital twenty seven hours later, on Sept 2 She was then in absolute coma and totally unable to swallow, mouth and tongue were dry and dirty , skin dry , dehydrated neck rigid but otherwise general flaccidity Abdominal reflexes absent Left sixth cranial nerve paresis The C S F was very purulent and contained meningococci of group I in films and culture Immediate treatment was 2 g sulphathiazole (40 c cm of 5% sodium solution) intravenously followed in two hours by 1 5 g by mouth and then 1 5 g four hourly Fluids and drug were given freely by stomach tube and continuous drip rectal saline was also given Next day she was still in absol [illegible] moist sounds at the bases them: anxiety symptoms however should not be ielved The chief danger is that the patient will sideep his problems and use an organically determined ymptom to evade further responsibility Where ysterical mechanisms come into play and replace nxiety, the illness is likely to become progressively more ifficult to treat

PHYSICAL TREATMENT

Drug therapy of the acute neuroses has been dealt with a previous communication [2] Since that report we have ad to treat a considerable number of cases which had een acute and have now become chronic Treatment of n acute neurosis is almost as urgent as that of the acute bdomen Whether treated in hospital or not these hronic cases had received no adequate sedation in the cute phase and they had been returned to duty too soon. onversion symptoms had been allowed to persist, and arge periods of amnesia had been left untouched By he time they arrived for treatment here the neurotic eaction had become fixed and prospects of return to full uty were almost hopeless It is of the utmost importance that the acute neurotic should receive effective irst-aid as soon as he is seen

Apart from the treatment of acute panic reactions physical and biochemical methods have their place in speeding up recovery in the later stages As always the success to be expected depends on the previous personality, and good results cannot be expected from poor material In addition to sleep therapy, a modified form of insulin treatment is useful in some cases for breaking down the vicious circle of anxiety and loss of weight Increasing doses of insulin are given in the mornings up to a maximum insufficient to produce coma or hypoglycæmic excitement, followed three hours later by 12 oz of potatoes or 7 oz of sugar The treatment is without any of the risks associated with insulin coma and generally produces a rapid gain in weight and improvement in physical condition Furthermore, the insulin often exercises a sedative effect which may last for the whole period between administration and interruption

Full psychological recovery is rare without the restoration of good physical health The mere appearance of physical fitness is often deceptive and on inquiry remarkable changes in physique will often be found including loss of weight up to 2 or 3 stone In all forms of drug therapy the aim should be by a large intake of fluid and food, not only to abolish the anxiety but also to remedy the metabolic disturbances due to and conducing to, its continuation. Only when his normal physique is restored is the patient fully accessible to psychotherapy id rehabilitation

OCCUPATIONAL THERAPY

The occupational technique worked out at this hospital is been described by Cameron [3] Occupation is even ore valuable for the sub-chronic than for the acute eurotic, and for a stabilised return to a normal working vil life it is almost indispensable Its value as a straction from neurotic preoccupations can be used en during the operation of stress. Our patients were uch better when kept at work during air-raids than hen allowed to congregate in cover-points and places greater security When allowed to seek the greatest vailable security the men became preoccupied solely ith the desire of finding a Utopia where they would *feel* ife and from spending nights in open trenches the more anicky took to breaking bounds in order to sleep in ublic shelters Such breakdown of control has its enalty in heightened anxiety, and the remedy is to deal y sedation with the subjective fears which, rather than ie real dangers are the effective noxus

MEDICAL BOARDING

The problems of necessity for boarding and proper oarding category should be faced as early as possible for hey inevitably influence the line that treatment itself will ake. If invaliding is indicated the desire of the patient o evade further military service can be used to aid ecovery rather than to perpetuate illness, he can be old for instance, that he will be recommended for lischarge, but only when he has recovered from his symptoms A healthy civilian is of more value to the country than a sick soldier Problems of boarding have been more difficult of late, for now the position of the man boarded "C" is not much easier than that of one still marked "A" [4] We have found that men passed suitable for service not involving strain have been sent to guard points subjected to heavy bombing, which has promptly precipitated a new breakdown Suitable employment within the Army framework is difficult to find, even for the neurotic of fairly good personality; and mistakes are costly These tragedies would be fewer if the vocational recommendations of the psychiatrist had any force

We do not believe that invaliding out if done carefully will greatly add to the number of neurotic casualties or that there is any risk of an epidemic of neuroses Certainly the prompt removal of the constitutionally unfit from the Army aids its efficiency and obviates much chronic invalidism Since there are at present no pensions for war neurosis it is important that the neurotic should be re-adapted to a working life before the question of pension arises and owing to conditions in the labour market this is much easier now than it will be when peace comes After this war the country must not be burdened with the large numbers of pensioners that crowded psychiatric clinics and Government hospitals for many years after the last war who are indeed, still with us A proper settling of the questions of attributability is still awaited, but when the time for this arrives it is to be hoped that the authorities will not lose sight of the malignant influence that the award of a premium for illness exercises on the neurotically predisposed

SUMMARY

The principal conclusions derived from the investigation of a large number of military neurotic casualties are :—

1. The nature of the material admitted to hospital varies with the progress of the war and with the different types of strain that war from time to time imposes Similar variations can be expected in the future

2 At times large numbers of cases will be seen in which there is a semi-deliberate magnification of symptoms

3 Treatment has to be adapted to what is possible in a short space of time It should not be aimed too high

4 Psychotherapy is faced with unusual difficulties in war-service cases Both from the structural and therapeutic points of view they closely resemble with specific differences, unsettled compensation cases of peace-time Quick abreactive techniques have a special value Special problems are offered by cases with aggressive tendencies and those arising after head injury

5 Medical first-aid is of the utmost importance Physical methods of treatment are very useful, and should have as a principal aim restoration of normal metabolism

6 Occupational therapy is also valuable even more for chronic than for acute cases

7. Over-optimism is to be avoided, and too much resistance should not be offered to invaliding the patient The constitutionally unfit must be weeded out of the Army, and for his own sake the unfit soldier should be returned to civilian life fit for work as early as possible

---

[2] Sargant, W and Slater E. *Lancet* 1940 2 1

[3] Cameron K. *Ibid* p 659

[4] Roughly speaking categorisation as A signifies that the soldier is fit for all duties as B that he is fit for all duties within limits (e g that he should not be submitted to great strain and exposure) and as C that he is fit for home service only

---

The Minister of Health on Jan 17 in a broadcast appeal to nurses said that now during the coldest winter months was the time for those who have had training and experience in fever and tuberculosis nursing to give their special help to the nation. We needed fever fighters as well as fire-fighters Nurses who were employed in any branch of the public health services should stay where they were but fever nurses who were employed in some other form of nursing should speak to their matron and write to him at the ministry or to the Secretary of State for Scotland at St Andrews House, Edinburgh. Members of the Civil Nursing Reserve who were unemployed at the moment would be temporarily released from their obligations if they were needed in the epidemic season.

Treatment has three practical goals to deal with the symptoms and to bring about a return to the condition before the breakdown, to re-adapt the patient to a socially valuable life, and so to arrange his future that strains that are for him intolerable will not have to be endured again If this can be done within the framework of Army life, so much the better, if not there must be an effective re-adaptation for civilian life The Army is not organised to provide a shelter for neurotics, and neurotic casualties throw more grit into the machinery than a corresponding number of organic casualties It is no good sending back into the Army, merely because he is symptom-free, a man who is liable to break down under small strain It is necessary, by accurate history-taking and a quantitative as well as qualitative diagnosis, to make an assessment of the personality and of the strains that it is and is not able to support Judgment is more likely to err towards optimism than in the opposite direction, for there is a natural bias against invaliding any man unless it is absolutely necessary Each one of us has seen return cases of men who had been sent out fit for home service and had unexpectedly proved unfit even for that They had gone to their units, had spent weeks on light duty or no duty at all, no-one knowing what to do with them, and had caused great trouble and difficulty before they were finally returned to hospital, disgruntled and resentful The longer a neurotic reaction is allowed to persist the more difficult it is to deal with, among the neurotically predisposed, emotional attitudes such as disgruntlement, panic, or scrimshanking are highly infectious Every consideration urges, therefore that if treatment is to be effective it must be quick, and limited to an aim that is quickly obtainable

PSYCHOTHERAPY

Psychotherapists will agree that the most important factor for the success of treatment is a real desire on the patient's part to get well, even when that involves a degree of sacrifice and a painful self-realisation The reward is a greater freedom from hampering difficulties, a greater capacity for enjoyment and a knowledge and acceptance of those fundamental circumstances which are incapable of change The military case, however, differs from that of peace time in that treatment encounters the same difficulties but does not offer the same reward, and that illness can secure a fundamental change in life, which is not otherwise to be obtained The soldier is uprooted from an environment to which after years of painful endeavour he has made some sort of adjustment, even if a neurotic one, he is forced through a military mill and subjected to previously unimagined strains Then, when illness comes, it may be weeks or months before even the possibility of treatment is reached By the time he reaches the psychiatrist he is a man with a grievance, sullen or apathetic And all the reward that is offered for cure is, to his mind, the privilege of returning to the scene of his failure in the knowledge that he has failed

Treatment, then, is faced with unusual difficulties, and must be pragmatic In late and less favourable cases it is wise to limit its aim to getting the patient well enough to return to his job as a civilian The patient is best told that he will be recommended for discharge, and an attempt is made to show him that his grievances are understood, and to remedy any sense of failure or worthlessness he may have acquired He needs to be assured that he can serve his country equally well as a civilian, and there are few who are not eager to accept this point of view Most of those who have broken down after little or no strictly military stress have to be so treated, and so have veterans of the last war, of whom significantly many have a history of previous "shell-shock" There is more hope for those whose breakdown has been precipitated by promotion or by the conflict over putting in for it, but care must be exercised here, as a seemingly situational neurosis may be firmly rooted in the personality

AMNESIAS

In the acute war neuroses there is a considerable tendency to spontaneous recovery But even if acute symptoms abate, an effort should be made to clear up amnesias and to let the patient re-experience the violent emotions that battle scenes have aroused This process —abreaction—has a prophylactic as well as an immediate therapeutic effect It may be induced by various me according to taste and experience The slow intraven administration of a suitable narcotic (such as sodi amytal gr 5–7½) is quick, effective, and of partic use to those unversed in hypnotic and analytic techniques Before it is begun a good rapport must be established and cooperation gained The patient should be told that certain painful memories are buried in his mind and are responsible for his symptoms, and that he will get better when they are dealt with The abreaction under the drug may be sudden and violent, in which case it is essential to give the patient time to weather the emotional storm, and to help him by an attitude of understanding and detachment At other times it may be necessary to use firm and persistent questioning to overcome resistance Sometimes actual memories are falsified by or mixed with fantasies, this may be made use of in subsequent interviews in giving the patient insight into the deeper causes of his anxiety Other varieties of behaviour under narcosis have been observed Tremors, stammers and other conversion symptoms usually disappear under the drug, and an attempt should be made by suitable suggestion, and by continuing the interview until the patient is fully conscious, to prolong the improvement into the waking state Though much may be done in one session, it is nearly always necessary to cover the ground again, exploring deeper into obscure episodes, laying bare amnesias previously unsuspected relating specific anxieties to the forgotten events and familiarising the patient with the emotion he has suppressed

The psychopathology of war neuroses is more complex than has been described by some writers who gained their experience in the last war Apart from the nature of the precipitating agent, the structure of the cases seen so far especially late cases with much anxiety and depression has resembled that of the occupation and post-traumatic neuroses of peace Differences are shown in the striking regressions that often follow being oneself, or seeing others, blown up, and in the temporary disturbance to the sense of reality caused by the bizarre effects of high explosive The most fantastic dreams are suddenly realised, as though by magic, in actual life, and the mind regresses to primitive mechanisms appropriate to the time of life when such fantasies seemed real The experiences of war provide a stimulus to aggressive and sadistic impulses, with the consequence that guilt and its associated depressive affect are very common, or projection mechanisms may come into play, the man believing that every 'plane is coming specially to punish him The therapeutic aim is then to make him aware of latent hostilities, to give him an opportunity of expressing them in a reasonable way, and to increase his confidence in his powers of control

HOSTILITY

Special problems are offered by the patients who show a marked hostility during treatment in hospital The aggressive reaction may be that of a constitutionally unstable personality to an unfamiliar environment These men have been social misfits all their lives, and their neurosis is the expression of failure to adapt to the Army, their asocial activities in hospital are usually childish, they defy discipline, or break bounds without reasonable gain—behaviour which is difficult to deal with, and has a bad effect on others of better personality As the prospect of a useful Army career is usually minimal, it is well to secure their discharge at the earliest possible moment, and to give them priority when it comes to boarding Aggressive reactions with a paranoid tendency are also seen in men of comparatively good personality with acute anxiety state, usually during recovery from the acute stage of the illness The phenomenon is part of the illness, and is to be treated as such In many of our cases it could be regarded as an over-compensation for loss of self-esteem, as the meaning of the illness became clear

Cases complicated by an organic factor offer special problems Neurosis commonly follows a post-concussive state and it is important to decide how far the influence of the injury extends It is harmful to keep patient in bed for more than two or three weeks in an attempt to prevent post-concussive headaches, the subsequent illness is more prolonged It is well to acknowledge that headaches do occur after concussion, but to make little various species of laboratory animal have shown that fferent animals vary in their susceptibility to blast d that animals exposed close to an explosion suffer ore than those further away Small mammals like bbits are usually killed instantaneously at excess essures greater than 50 lb per sq in At higher essures close to the explosion they would be blown to eces while at slightly lower pressures they survive for a ief period their symptoms during the interval they ve after exposure usually including dyspnœa and chypnœa Blood-stained froth is also occasionally esent in the upper respiratory passages of such imals while knee-jerks corneal and pupillary reflexes e normal immediately after an explosion Animals xposed to slightly lower pressures do not die and xternally appear to be unaffected by the explosion nternally, however they exhibit changes in thoracic nd occasionally abdominal organs At still lower ressures (e g excess pressures of 5 lb per sq in) nimals are affected neither externally nor internally

The most outstanding lesions are hæmorrhages vary-ng in extent on the surface and in the substance of the ngs When animals have been exposed to minor egrees of pressure lesions are slight. whereas the lungs f animals exposed to high pressures may be one mass of æmorrhage Lacerations are also found The lesions re detectable radiologically. and they clear up fairly apidly Hæmorrhagic lesions are also occasionally bserved in the thymus in the pericardium and epicardium In about 40% of cases in which pulmonary æmorrhages occur hæmorrhagic lesions are also found n abdominal organs The most susceptible abdominal rgan is the large intestine Hæmorrhages (and ccasionally lacerations) have also been observed in the mall intestine and stomach the liver the spleen the idney the adrenals the bladder and the uterus while etroperitoneal as well as intraperitoneal hæmorrhage may sometimes be present In the head hæmorrhages have been observed in the fascial planes of the orbital cavity and at high pressures the ear-drums may be ruptured The central nervous system appears to be affected only at relatively very high pressures No lesions have been observed in the brains of monkeys which however show hæmorrhages around the spinal roots, especially in the thoracic region A zone of œdema around the central canal is also generally observed in monkeys exposed to high blast pressures In rabbits the nervous system appears to be more sensitive than in monkeys and apart from spinal-cord changes pial and ventricular hæmorrhages have occasionally been observed on and in the brain of these animals

Experiment has shown that the pulmonary and abdominal lesions are due to the impact on the body wall of the pressure component of the blast wave Thus animals exposed to explosions so that one side shields the other receive lesions only on the side facing the explosion . while animals whose body walls are clothed in a sufficient thickness of sponge rubber are far less injured internally than are controls The unilateral disposition of the lesions according to the circumstances of exposure argues against any theory which postulates that the lesions are due to some general effect—for example to pressure changes occurring by way of the upper respiratory tract Observation has also shown that fat emboli are not present in the lungs of animals killed by blast, and that the lesions cannot be attributed to back pressure in the pulmonary circuit even though such pressure does cause hæmorrhages which in some respects are similar to those caused by blast The pulmonary and abdominal injuries due to blast may thus be compared with those which occur without open wounds as a result of severe falls or direct blows to the body wall

Turning to the clinical aspects Professor Zuckerman pointed out that in air-raids people are exposed not only to the direct effects of blast but also to indirect effects such as violent displacement secondary missiles and falling masonry A specially conducted casualty survey has shown that the direct effects of blast such as have been observed experimentally are experienced only close to an explosion, and it follows that relatively few people who have been injured in air-raids can have been exposed in circumstances where they would have received primary blast injuries Pulmonary hæmorrhages cannot be regarded as an exclusive sign of primary blast injury which can only be diagnosed when the full circumstances of injury are known Cases that have been described as primary blast effects may indeed have been due to such secondary blast effects as violent falls or the impact of flying masonry

He gave examples of people who had been killed by the direct effects of blast of people whose death was due either to a combination of primary and secondary effects or to secondary effects alone and of people who had received non-fatal internal injuries as a result of the impact of a blast wave Physical signs are not prominent in such cases which are however detectable radiologically In making diagnoses of blast injuries Professor Zuckerman suggested that attention should be paid to the condition of the ear-drums which would probably be ruptured at the higher blast pressures that cause lung injuries

Prof **Geoffrey Hadfield** reported on 30 post-mortem examinations that had been carried out on victims of air-raids In some 8 of these there were no significant external injuries and in 4 pulmonary hæmorrhages were associated with a high degree of carbon-monoxide saturation of the blood Of the 30 2 had died of compression asphyxia and 3 from asphyxia due to the inhalation of the dust of debris 22 showed pulmonary hæmorrhages which were rarely marked on the surface and which were sometimes extensive within the substance of the lungs Rupture of alveolar walls was not a prominent microscopic finding and as a rule alveoli filled with blood had intact walls The primary lesion in these cases was he felt a widespread dilatation and congestion of the alveolar capillaries from which diapedesis probably occurred into the alveoli His observations suggested that hæmorrhagic lesions are usually more extensive in people who do not die immediately than in people who are killed . and he felt that bleeding may continue into the lung for at least 48 hours after exposure to blast causing consolidation of large areas Consolidation is often associated with leucocytic and monocytic infiltration Professor Hadfield pointed out that his remarks were founded on what he described as a very short experience and in view of Professor Zuckerman s observations about the similarity of internal injuries due to blast and those due to violent falls or the impact of falling or flying masonry he did not claim that the cases he described were due to the direct effects of blast There is little opportunity for obtaining suitable material for investigation, and it is therefore difficult to sort cases and disentangle the incident The observation that bleeding into the lung may continue for days is he felt significant since it means that patients with symptoms suggestive of lung injury should be kept immobile and treated as for hæmoptysis

Dr J N O **Reilly** described 3 non-fatal cases which he had treated and emphasised that within a very short period they had become apparently ordinary clinical lobar pneumonia In 5 other patients who were brought in from the same incident the appearances were those of an acute abdominal catastrophe In 2 of them symptoms were sufficiently pronounced to justify surgical intervention but nothing was found at operation except a few minute subserous hæmorrhages. Dr J M **Alston** inquired whether animals which survived exposure to blast manifested signs of pseudopneumonia similar to those described by Professor Hadfield in humans and Dr **Beryl Barsby** referred to 2 air-raid casualties whom she had treated and in whom internal injuries including a spontaneous hæmothorax appeared to be due to blast

In replying Professor **Zuckerman** remarked that although hæmorrhagic lesions in the lungs often appeared to be better demarcated in animals which survived than in animals immediately killed by blast there was no evidence that the bleeding continued in the sense of an extension of primary zones of hæmorrhage Consolidation of the lungs associated with leucocytic and monocytic infiltration had been observed in animals and appeared to be similar to the changes described by Professor Hadfield In conclusion. he re-emphasised the point that without knowing in detail how a casualty had been injured in an air-raid it was impossible to decide whether lung damage was due to the primary or secondary effects of blast. or to a combination of both

A PNEUMOCOCCUS WHICH REQUIRED CO_2 FOR ITS GROWTH

By Alexander Fleming, M B Lond , F R C S
PROFESSOR OF BACTERIOLOGY IN THE UNIVERSITY OF LONDON AT ST MARY'S HOSPITAL

At this season many bacteriological examinations are being made in connexion with respiratory catarrhs, and in the light of the experience here detailed it seems possible that certain important organisms may be completely missed by ordinary methods of culture

A laboratory worker contracted a “cold” The original clear discharge from the nose had by the fourth day become very profuse and mucopurulent A casual examination of a gram-stained film of this discharge showed many capsulated diplococci, but cultures made on blood agar and on boiled blood agar gave a pure growth of *Bacillus influenzæ* (Pfeiffer) The next day a fresh sample of mucopus was examined microscopically with greater care, and in addition to capsulated gram-positive diplococci many small gram-negative bacilli resembling *B influenzæ* were observed Cultures on blood and boiled blood agar again gave pure growths of *B influenzæ* These examinations were repeated on the next two days with exactly the same results

The position, therefore, was that in the nasal pus there was a heavy infection of what appeared to be a pneumococcus, which had on four separate occasions refused to grow on a culture medium which should have been suitable (5% horse-blood agar) At this stage I remembered having been informed by Dr Gleeson White at a demonstration given at a laboratory meeting of the pathological section of the Royal Society of Medicine that some pneumococci required for their growth an atmosphere containing an increased amount of CO_2 I therefore planted the nasal pus on two blood plates, one of which was incubated in the ordinary way, and the other in an atmosphere containing roughly 10% of CO_2 The plate incubated without CO_2 again gave a pure culture of *B influenzæ*, whereas on the plate grown with CO_2 there were in addition numerous large mucoid colonies of pneumococcus which proved to be of type III The same procedure was repeated five times during the next week, always with the same result These results clearly show that there are pneumococci which do not appear in culture on blood agar unless an increased amount of CO_2 is present in the atmosphere

The method used for growing the organism in CO_2 was very simple The container was a metal can with a “push in” lid wide enough to hold the culture plates, and with a total capacity of about 2 litres The inoculated plates were placed in the can, CO_2 was run in from a Kipp's apparatus, and the lid firmly replaced, but not sealed in any way On different occasions amounts of CO_2 from about 100 c cm to 300 c cm were added, and with all there was the same copious growth of the pneumococcus There is, therefore, considerable latitude in the amount of CO_2 which may be added

The pneumococcus was subcultured daily on blood agar slopes which were incubated in air and in air plus CO_2 For the first three days there was no growth without increased CO_2 in the atmosphere The fourth subculture grew (badly) in air, the fifth better and the sixth grew equally with and without added CO_2 The first four of these subcultures were, of necessity, made from the culture grown in CO_2 The remaining ones were made from the cultures obtained in ordinary air

The colonies obtained in CO_2 from the original muco pus did not differ in any perceptible way from ordinary type III pneumococcus colonies When the organism was acclimatised after six subcultures the colonies in ordinary air were perfectly normal type III colonies

This series of observations is striking in that on ten separate occasions the pneumococcus which could be seen in nasal pus failed to grow on blood agar when incubated in the ordinary way, but grew well when CO_2 was added in every one of six trials In clinical bacteriology it is the custom to examine films of nasal secretion or sputum when such are sent to the laboratory, and thus the cultural results are checked It is not, however, so common for postnasal or throat *swabs* to be examined microscopically and if this is not done there may be a pneumococcus (or other organism) which will not grow except when CO_2 is added, and such an organism wo be completely missed, even if it were the most importa part of the infection

A number of postnasal swabs have been cultured blood-agar plates with and without added CO_2, and in case was an organism found which grew less luxuriant in an atmosphere of 5–10% of CO_2 It might, therefo be an advantage to incubate all cultures from th respiratory tract in this way The technique is easy a does not involve any serious expenditure All that wanted is a reservoir of CO_2 (a Kipp's apparatus, or cylinder of the gas) and a metal can of suitable (such cans are used as containers of children's foods a other things) The CO_2 reservoir can even be done aw with by adopting the procedure described by Glad and Fildes[1] (1940)

The observation that some pneumococci will not gr unless CO_2 is added is not new I have already me tioned that Dr Gleeson White made a similar observation, and Khairat[2] found in blood-cultures certai organisms, including one pneumococcus, which gre badly or not at all unless with added CO_2 In spite of th it does not seem to be generally known among bacteriologists that these cultural requirements exist

CONCLUSIONS

The lessons to be learnt from this case are

1 The simple microscopical examination of infecte material should not be omitted If the nasal mucop from the case cited had not been examined microscopically it is likely that the profuse pure culture o *B influenzæ* would have satisfied most bacteriologi that there was a simple *B influenzæ* infection, but th examination of a gram-stained film made it at onc obvious that the culture gave a misleading picture

2 Even on what is regarded as a suitable cultur medium a common organism may fail to develop unle CO_2 is added to the atmosphere

Medical Societies

ROYAL SOCIETY OF MEDICINE

At the joint meeting of the sections of Surgery an Pathology on Jan 8, with Mr J B Hunter in the chai a discussion on the

Problem of Blast Injuries

was opened by Prof S Zuckerman who gave account of experimental work carried out by member of the Department of Human Anatomy Oxford, for th Research and Experiments Department of the Mini of Home Security It has become recognised he sai especially since the Spanish war, that the blast of hi explosives can kill or injure people without cau external injuries, in such cases the most prominen internal lesions are hæmorrhages in the lungs Simila pulmonary lesions and hæmorrhages in parts of th central nervous system and in some abdominal orga have been observed during the 1914–18 war in exper mental animals that have been exposed to blast T understand how these lesions occur it is necessar know something about the nature of blast When high explosive detonates a relatively small amount solid becomes converted almost instantaneously into very large volume of gases which by their expansi produce a blast wave in the surrounding air The wa is a single pulse of increased pressure followed by phase of suction, and it moves very rapidly, falling, the case of a medium-sized bomb, to the velocity sound (1120 ft per sec) at about 200 ft from t explosion The total duration of the whole wave at a given point is brief the pressure component close to charge seldom lasting more than 5 millisec , and t suction component about 30 millisec The maximu pressure of the wave is highest in the region of t explosion but it rapidly falls, especially at first t further the wave moves Thus excess pressure in t neighbourhood of a heavy explosion may be as much 150 lb per sq in whereas 50 ft from the bomb t excess pressure may be no more than 5 lb Experimen

'JELONET' TRADE MARK BRAND

PETROLEUM-JELLY GAUZE DRESSING

'Jelonet' is made from a specially woven open-mesh gauze, evenly saturated with petroleum jelly and Balsam of Peru, and is packed in sealed containers of 24 dressings, sterilised ready for immediate use

'Jelonet' is indicated for Skin-Grafts, Compound Fractures, Burns, etc., as a non-adherent dressing to promote granulation

The open-mesh dressing encourages free escape of discharge, and ensures ventilation of skin-grafts and the young epithelium, with minimum trauma to granulations

Uniform saturation with petroleum jelly prevents serious rise of temperature due to toxic absorption, secondary dermatitis of the surrounding skin arising from irritating discharge and also permits ready extrusion from deep wounds

Obtainable through your usual surgical supplier, 5/2d per tin of 24 dressings Special discounts available to Hospitals

ASSOCIATION OF CLINICAL PATHOLOGISTS

SCIENTIFIC MEETING WITH DEMONSTRATIONS

AT the Sir William Dunn School of Pathology, Oxford, on Jan 4, Prof A D GARDNER demonstrated the diagnostic work—now centred at Oxford in the Emergency Public Health Laboratory Service—on specimens of sera received from patients thought to be suffering from infection with *Leptospira icterohæmorrhagiæ* Specimens of sera from the pre-jaundice stage were wanted It might be possible, he suggested, to make an early diagnosis from the extreme weakness in the febrile stage, muscle pains, photophobia with red conjunctiva, and vomiting The work of most of the patients hitherto examined exposed them to direct infection from rats—e g , sewer men, canal hands, farm labourers and a pumper from air-raid shelters

Dr JOAN TAYLOR demonstrated the identification of the various salmonellas by preliminary cultural tests followed by serological analysis with the standard specific and group-agglutinating sera She would prefer to call these by their figure and letter constituents rather than the town or district of origin She discussed slide and tube methods of titration of agglutinogens , both, she said, were needed Craigie's use of a small inserted tube in a culture tube of " sloppy agar " often provided rapidly, from the top layer of the surrounding agar, culture of the most motile bacilli required for testing the flagellar H element

Dr A H ROBB-SMITH demonstrated the histology of lymph nodes Glands from the inguinal region were often too fibrous while those from the upper cervical chain might show a confused picture owing to former inflammation from teeth and tonsillar lesions , the best gland should be chosen by the clinical pathologist generally one from the lower cervical chain or the axilla The whole gland should be carefully excised and immediately fixed Section before fixation enabled the capsule to retract and so distort the finer details of structure sought by the pathologist in the follicles, sinuses and medulla of the gland

Dr C L COPE resumed his work on pregnandiol (LANCET, 1940, 2, 158) The absence of pregnandiol in the urine after a threatened miscarriage, he said, enabled the gynæcologist to assume with some confidence that the fœtus was dead

Captain L HANSEN described the estimation of the amounts of sulphanilamide, sulphapyridine or sulphathiazol present in the blood after their administration either orally or parenterally Difficulties arose because the same dose in different patients might yield different concentrations in the blood, or even in the same patient on different occasions The conjugated acetylated forms of the three substances were inactive Even a trace of Novocain, accidentally admitted from the needle used to the specimen, might falsify the colorimetric determination

After dinner at Oriel College a discussion took place on the regionalisation of hospitals in the future and its effect on clinical pathology Much emphasis was laid on the direct relationship that should exist between the pathologist and the patient the sending of specimens by post and the resulting divorce of the pathologist from access to the patient was deplored

Reviews of Books

Surgery of Modern Warfare

Part 2 Edited by HAMILTON BAILEY, F R C S Edinburgh E and S Livingstone Pp 160 12*s* 6*d*

WITH the publication of part 2 " Surgery of Modern Warfare " gets fairly into its stride The chapter on skin grafting is completed and there are full accounts of the war surgery of the chest, abdomen, genito-urinary system and arteries The overlapping and contradictions which to some extent marred the value of part 1 are here nowhere in evidence A battery of experts fire their salvos with precision and effect, and Mr Hamilton Bailey is well justified in saying " What they have to say must be authoritative " For all that a contributor, however eminent, should spare us such expressions as " Plurivisceral damage augments mortality , multiregional injury determines a heavier death-roll " The chapter on wounds of the chest covers most of the ground in a short space The genito-urinary system is discussed by four authors each of whom has given us a clear and concise account of the problems involved in this branch of surgery The final chapters deal with the surgery of the arteries and include a discussion of the different types of tourniquet in common use The two chapters on the surgical approach to the arteries are stimulating The author of them has wisely assumed that the anatomist, not God, decided that the third part of the axillary artery should become the brachial artery at the lower border of the teres major , and that to describe two methods of approach to this continuous structure is superfluous Throughout, the essentially practical methods of Fiolle and Delmas have been preferred to the classical approaches described by most textbooks Thus long skin incisions are advised , the free dissection of tendons and fascia with, if necessary, resection of bone gives the operator a chance to examine carefully the exact source of the bleeding and allows him to ligature only such vessels as require it, thus saving needless sacrifice of the blood-supply to a limb which might otherwise be in danger of gangrene

Duval's approach to the first part of the anterior tibial artery and Sencert's and Henry's approaches to the first part of the subclavian artery are operations which should only be attempted by the expert working in a properly equipped theatre The first may save a limb when the more simple ligature of the popliteal artery might cause gangrene Ligature of the first part of the subclavian is a life-saving measure and these approaches should be mastered by the surgeon By the perfection of such operations our results will improve In the last chapter two problems worthy of further investigation are treated, perhaps a little too authoritatively, as settled The first relates to simultaneous ligature of the vein when the main artery to a limb is ligatured, about which there are still differences of opinion Secondly, it is advised that a limb in danger of gangrene should be kept at room temperature and not warmed, the argument being that by increasing the temperature of the limb the metabolism of the part is increased and this may be too much for a flagging circulation to control The circulation is certainly improved by warmth however and the question is whether this augmented circulation is in proportion to the increased metabolism, whether it is in excess of the demands or whether it falls short of the new metabolic requirements Fresh investigation is necessary before this extremely important point can be decided Finally, although many surgeons will not share Mr Hamilton Bailey's passion for *maggots* (a *long chapter* on which is included) most will understand his reasons for saying " I have learnt more in editing part 2 than by taking a postgraduate course visiting surgical clinics "

War Wounds and Injuries

Edited by E FLETCHER, M B Camb , M R C P , physician in the E M S and to Queen Mary s Hospital for the East End , and R W RAVEN, F R C S , surgeon in the E M S and to outpatients at the French Hospital, London London Edward Arnold and Co Pp 255 14*s*

THIS is a collection of articles on the surgery of wounds and injuries that have appeared in the *Postgraduate Medical Journal* during the first year of war It is therefore a symposium rather than a textbook, a series of essays rather than a comprehensive review Some of the contributions are written for the young general surgeon, others are more suitable for the expert The discussion on injuries of the eye and disturbances of vision which occupies sixty pages is of interest above all to the specialist On the other hand, in the chapter on war injuries of the jaw and face Cole deals with principles rather than details, and gives an insight into the problems of these important injuries that is essential to the surgeon who may have to deal with them in the front line The excellent group of papers on injuries of the chest by Roberts, Sellors Price Thomas and Alexander should be very helpful to the young war surgeon, and the slight divergence of views on hæmothorax does not detract from the value of the discussion as a whole Other contributions of real practical importance, because of their sane outlook and their emphasis on principles, are those on amputations by Seymour Barling, on the surgery of deformities by MacMurray, and on injuries of the spine and spinal cord by Knight

TEACHING OF FIRST-AID

WE are beginning to see that our teaching hospitals ust become educational centres for everything con- rned with the art of healing. Evolution along those nes has developed considerably in the last fifty ars the dental school was attached to the medical hool the nursing, massage and radiographic schools veloped in turn, but nowhere has there yet arisen e complete school of healing, where all, except a few niors are learning their jobs and passing on to take o posts in other institutions. A new stage in the volution of a fully comprehensive school has been ached at Queen's Hospital, Birmingham, where a hool for training industrial workers in first-aid is to e established as part of the Accident Hospital and ehabilitation Centre primarily to meet the needs f firms not large enough to have their own trained urse or doctor. Here trainees will live in the ospital for a fortnight and act as nursing orderlies. he need for such training centres extended to meet he needs of first-aiders both inside and outside the actories is evident, for though first-aid parties are oing and have done valuable work in air-raids it can carcely be said that all is well with first-aid. Every loctor of course has his funny story of how the first- ider shouldered him out of the way, but this would ot matter if confidence and competence always went and in hand.

Training of first-aiders in England has been under- aken by the St John Ambulance Association and the British Red Cross. The first is primarily a peacetime organisation and the second, though designed for war has been chiefly active in training volunteer nurses for hospitals. The textbooks of neither were designed to meet the type of problem presented by air-raids, and the only widely circulated book written to that specific end is the A R P Handbook, No 10.[1] The result is that training of first-aid parties to meet present emergencies starts with an initial handicap of a syllabus and an examination unsuited to the needs of the moment. Medical lecturers are not devoid of blame. One at least read the book to the class without comment, another occupied half an hour of a four-hour course to wardens in explaining the psychological theory of shock; and another advising on treatment, startled his hearers by remarking "Just inject a little strychnine—you can't go wrong." Nor are these isolated instances. We can all recall lecturers, able clinicians, whose teaching ability was non existent. This is not beyond remedy, for teaching is a job with a technique that can be acquired, lecturers must realise this, and remember that the presentation of the facts is as important as the facts themselves. Those who have been teaching or examining first-aiders in recent months are well aware of the recurrent faults of candidates and of doctrine. The avidity with which tourniquets are applied, the unpadded splint hard on the malleolus, the single (proprietary) disinfectant of which they have heard the fumbling for pressure-points, the incompetent Schafer's method—how familiar they are. Most dangerous of all, perhaps, is ignorance about shock. A correspondent writes "The first candidate who knows when shock appears and that its effects can be explained from the reduction of blood-volume wins a bottle of beer or a box of chocolates—but we have not had to present a prize in two years." First-aid needs a background of sound first principles or it cannot be applied intelligently, and sometimes even the lecturer lacks the background.

How the proper training and teachers are to be obtained is not easy to answer. An M O H recently expressed the opinion[2] that it is desirable for all members of first-aid posts to be sent to casualty departments for training, and only those who can devote sufficient time to gaining this experience should be retained at the posts. On another page an account will be found of a scheme for a national school giving a fortnight's intensive course in similar fashion to the A R P schools. The proposal is attractive in many ways, but has the questionable purpose of training lay instructors. If the first-aid training now given by doctors is unsatisfactory, training given by lay instructors would scarcely be likely to improve on it. The scheme, however deserves full publicity so that its strengths and weaknesses can be gauged. In the first place is a fortnight long enough to teach anyone anything in such a way that it will stick? Those who have lectured to nurses know that it is not until the second year that facts learned in the first year become everyday equipment in the student's mind. Only by working with new knowledge over a period of time can we convert it into a familiar tool. A fortnight's course of the kind would be excellent for doctors about to teach first-aid, if they could be induced to take it. They would have both knowledge and experience already, and would need to be told only what was relevant to their purpose and how to present it. But for lay first-aiders some longer preparation is surely necessary. Possibly the student could split his fortnight's training, starting with a week of intensive study and practical experience, under supervision, in clinics and outpatient departments, then returning to his own district for six months to attend routine night or week-end classes designed to stamp in his hastily acquired knowledge and technique, and finally spending a second week at the school for revision and further practical experience before sitting for his examination. Some such system would ensure a competent standard, but first-aid is unsatisfactory at present because it is badly taught, and our first step must be to ensure that the teachers learn how and what to teach.

MANAGEMENT OF SECONDARY SHOCK

CURRENT opinion on the treatment of wound shock is expressed in the Medical Research Council memorandum[3] which says that "the most important single requirement for arresting the progressive deterioration is restoration of blood-volume." This opinion is justified by the experience of the Army Blood-transfusion Service with air-raid casualties. But the

oidemic influenza in the south-eastern states at it the same time

rological differences amongst influenza A viruses been recorded by several workers but there is ys an unmistakable antigenic overlap, virus B he contrary is serologically quite unrelated to A ems to be biologically similar in that it will infect ets and mice, but both the primary transfer from to ferret and the subsequent infection of mice a ferrets are more difficult than with A only one in of B has in fact been securely established in ets and mice Sera from patients convalescent n outbreaks of influenza B have shown a specific in neutralising antibodies against B and not inst A Existing evidence as to the prevalence B is based thus far on serological evidence of this rather than on actual isolation of the virus ANCIS deduces on this basis that an epidemic he died in California in 1936[3] was probably caused influenza virus B and it appears also that the ne virus was concerned in an outbreak in the st Indies last summer

This last finding raises a question of much epidemiological interest, for the West Indian outbreak was parently due in the main to influenza A virus is is not the first occasion on which different viruses ve been isolated from one influenza outbreak UART-HARRIS and others[4] recovered several distinct rological strains of virus A from the epidemic in itain of 1936–37 and similar findings are on record om North America and Australia The 1939 outeak in this country was only to a minor extent used[5] by virus A possibly B was the chief villain that year It will doubtless be diligently sought r in this country Difficulties encountered in 1939 emed to set back our hopes of finding a differentiaon between epidemic influenza and febrile itarrhs which should have both a clinical and an tiological basis Now that influenza B is on the iap we must recognise that the problem is even more omplex than it looked a few years ago and must try ot to lose patience with those who are trying to nravel the tangled skein

ARTERIO-VENOUS ANEURYSM

WAR lends special interest to arterio-venous neurysms for most of them come from gunshot ounds Two recent papers by observers who have isagreed before show that this condition is still nperfectly understood Sir THOMAS LEWIS[6] reports bservations on three men wounded in the last war His paper is mainly concerned with the compensatory hanges in the affected limb whereby its circulation s restored to normal or more than normal Diminuion in vasomotor tone is found but does not account or the whole increase in blood flow which LEWIS is nclined to attribute to vascular growth in response o a local chemical stimulus For the surgeon the oint of immediate interest is that here are three ases all of some twenty years' standing without any ardiac breakdown resulting from the fistula One of them LEWIS has reported before[7] and he estimated that the leak from artery to vein in this case amounted to half the cardiac output It is true that these men are not free of symptoms but such as they have are not due to cardiac failure Prof EMILE HOLMAN[8] reporting nine cases in addition to twelve previously reported deals with the problem from a surgical point of view He maintains that the risk of cardiac failure as a result of the fistula may be determined by the behaviour of the blood-pressure and pulse on digital occlusion of the fistula and he maintains that in a recent case an increase of pulse-rate and a fall of blood-pressure even if small indicates a large fistula which is almost certain to overtax the heart sooner or later He records two cases with heart-failure relieved by operation both of which had had a fistula for several years before developing cardiac symptoms Two of his other cases were of several years' duration without cardiac failure and the remainder were recent LEWIS S cases and some of HOLMAN S show that it is not easy to foretell the effect of the fistula on the heart and the possibility of cardiac failure can hardly be regarded as an absolute indication for operation With regard to the general effects of arterio-venous fistula HOLMAN says that the extent of the increase in blood-pressure and fall in pulse-rate produced by digital occlusion of the fistula is commensurate with the extent of dilatation of the heart and vessels proximal to the fistula being least when the fistula is of short duration and greatest in cases of long duration with cardiac dilatation In several cases he observed that the fistula was associated with an increased blood-volume which returned to normal after the fistula had been closed by operation Immediately after operation the same rise of blood-pressure and fall in pulse-rate occurred but these returned to normal with the elimination of the surplus blood-volume LEWIS and HOLMAN differ about venous pressure in these cases but they seem to agree that there is no rise in general venous pressure in the absence of cardiac failure Eight of HOLMAN's patients were treated by ligation or excision of parts of the main vessels of a limb but in none was there any impairment of the vitality of the peripheral tissues In all cases there had been developed an adequate collateral circulation, and as LEWIS's observations show, in a long-standing case it is more than adequate If surgery is decided on as soon as a diagnosis is made, time should be allowed for this collateral circulation to develop and in one of HOLMAN S cases operation was deliberately delayed for this purpose

---

MRS CRESWICK ATKINSON, a member of the Horder Committee and technical adviser to the Women s Voluntary Services, has been appointed to undertake social welfare work for women and children using air-raid shelters in London She will confine her work to shelters holding 500 or more, the needs in smaller shelters are thought to be different The appointment is a full-time one Mrs Atkinson will be assisted by a band of workers who will advise and guide the mothers in the new welfare problems created by shelter life She will work with Alderman Charles Key, M.P , the London regional commissioner for shelters

SINCE the publication of the last list of subscriptions to the Medical War Relief Fund £680 has been received, bringing the total to nearly £14 600 impressive observations recorded on p 99 by Colonel WHITBY and his associates in that service make it also clear that a low blood-volume cannot be restored by good intentions and a little fluid, the abolition of severe secondary shock often demands transfusion of almost unbelievably large amounts In judging how much to give these workers have come to rely chiefly on the blood-pressure They find that variation in the pulse rate and the other clinical manifestations of secondary shock are fallacious guides, whereas recovery of blood-pressure runs parallel with recovery of blood-volume—a finding checked in some cases by the simple hæmatological method of blood-volume estimation first used by ROBERTSON and BOCK[4] and lately exploited by officers of the Army Blood-transfusion Service The necessity for such an objective measure of the patient's needs arises partly from the possibility of giving too much rather than too little, for overloading of the circulation, with consequent pulmonary œdema, is a grave danger where large quantities of fluid are being pushed into veins As things stand, however, cases of shock run a far greater risk of death from insufficiency than from excess It is evident that transfusion can save cases that are otherwise hopeless, and in future no one will be able to say that this remedy has failed unless the adequacy of the transfusion has been demonstrated by blood pressure records

[7] Lewis and Drury A N *Heart*, 1923 10 301
[8] Holman E *Ann Surg* 1940 112 840

In stating that transfusion can save lives we cannot pretend that the saving is wrought without much effort and planning in advance The five pints of citrated plasma used in some of the Bristol cases to restore blood-volume before operation represent the contribution of fifteen voluntary donors, and no organisation short of the elaborate transfusion services that have now been established could hope to provide sufficient amounts of the appropriate fluid with the promptness essential for the successful treatment of those who are badly wounded Secondly, even when the blood or plasma is readily at hand it cannot be used to full advantage unless there are good facilities The vital work of resuscitation after injury demands that between the reception-room and the operating-theatre there shall be distinct and ample intermediate accommodation where an experienced officer is able to direct a generous allotment of skilled help Here the more conservative measures for overcoming primary shock will be systematically applied, and may indeed prove sufficient except when casualties obviously need transfusion at once An initial delay is useful for differentiation between primary and secondary shock, while the patient will be able to bear the burden of secondary shock better if he is no longer suffering from primary shock in addition But if warmth, rest with the head low and smallish doses of morphia do not raise the systolic pressure above 100 mm Hg within an hour, or if fifteen-minute readings show deterioration, transfusion will be wanted When this decision has been taken and the transfusion has been given, and the blood-pressure and strength have risen enough to permit of operation, the patient may leave the resuscitation ward, but even now the need for watchfulness and action will by no means have passed Blood-pressure that has been reasonably restored may fall again during the delay sometimes inevitable before the surgeon can g
work, or through the action of the anæsthetic, o
an effect of the operation itself Apart from t
possibility of renewed bleeding there is the certa
that the watery citrate solution used to pre
coagulation of the blood or plasma will be rap
excreted from the circulation, and this fract
amounts to two-sevenths or more of the total vol
administered In view of this disposition to rel
the needle or cannula should not be removed from t
vein and the patient should be accompanied to t
operating-theatre by a slowly dripping bottle of b
whose transfusion can be accelerated at any mom
if need arises Ideally, a member of the resuscitat
team, perhaps a senior medical student, should foll
each patient from reception until operation is o
With a blood-pressure cuff in situ either this attend
or the anæsthetist can ensure that the patient reac
his final ward in good condition As to the choice
resuscitation fluid, the reports of the Army Blood
transfusion Service establish the safety of citrat
plasma, but their experience suggests that after even
two pints of plasma it is best to introduce a pint
blood Those who are accustomed to put their fai
in dilute plasma mixtures or in normal saline shou
remember that the action of these solutions on blood
pressure is short lived

Anyone who has treated air-raid casualties wi
appreciate the difficulty of collecting data as compr
hensive as those presented in our columns this wee
Amid the hubbub of the blitz the teams of the Arm
Blood-transfustion Service have managed to clear
metaphorical space for clinical research and have the
given their minds coolly to the principles of treatmen
and the verification of those principles in practic
If these and similar studies can be pursued they shou
soon enable us to answer far more distinctly the vexe
but fundamental question how far reduction in bloo
volume is the basic cause of secondary shock and ho
far other factors contribute The facts alread
obtained speak louder than words

INFLUENZAS A AND B

SINCE the successful inoculation of ferrets with
virus obtained from epidemic influenza patients i
1933, most of the more widespread influenza outbreak
throughout the world have yielded a similar vir
when it has been looked for But there has bee
increasing evidence that, apart from sporadic cases an
local outbreaks of clinical influenza, definite epidem
may occur in which this virus is absent or plays on
a minor rôle Workers at the National Institute f
Medical Research and at the laboratories of t
Rockefeller Foundation, New York, lately agree
to call the original agent "influenza A virus," and
keep a sharp look-out for yet undiscovered virus
B, C, and so on, or other agents which might
responsible for those outbreaks from which A is abse
They have not had long to wait FRANCIS[2] h
described "a new type of virus from epiden
influenza" which is designated "influenza B virus
This turned up in throat washings from patients wi
influenza near New York in February and March, 19
and evidence was obtained that it was also concern

2 Francis, T Jun *Science*, 1940, 92, 405

that is not always easy to differentiate from ntary resistance to flexion A diagnosis of "cerebral lenza" should never be other than provisional, ding a full clinical investigation which would necesly include lumbar puncture, blood-counts, and ibly radiography of sinuses It is doubtful indeed his diagnosis is justifiable at all in the absence of a l defined epidemic of influenza There can be no ological proof and the diagnosis becomes purely culative It has been common in the past to refer newhat loosely to nervous types of influenza arising connexion with an epidemic These are, however, re accurately described as cases in which nervous nptoms are prominent during or after the attack he term cerebral influenza is to be used, there should t be a reasonable probability of the influenza virus ng active in the neighbourhood, and secondly, the nptoms should include distinctively cerebral manifesions—for example, upper neurone paresis, convulsions Jacksonian type or coma Headache, delirium and casional slight neck rigidity are common to many rers and do not in themselves constitute a cerebral type

ALCOHOLISM AND DRUG TOLERANCE

We noted not long ago[1] that even the moderate drinker ust remind himself as he drinks his glass of beer that will play the devil with his leukotaxine and make him i easier prey for prowling bacteria Chronic alcoholism is its own drawbacks It is an old observation that ie heavy drinker is difficult to anæsthetise, and that the iæsthetist can, by noting the amount of ether required put him under, plumb the depth of his alcoholic past hlquist and Dille[2] have been experimenting to find out hether tolerance to alcohol affects the response to ther drugs, but since among the other traditional gures that hard times have banished are the two bottle nd three-bottle men they have had to fall back on rtificially debauched rabbits They produced tolerance o alcohol in these animals by injecting intraperitoneally 5 g of alcohol per kg body weight daily in 20% solution or 15–25 days This dose made the rabbits moderately ntoxicated, on human standards The first and last loses were given intravenously, and tolerance was onsidered satisfactory when the sleeping time after a lose was reduced to a half Tolerance to other drugs was estimated 48 hours later, by which time the residual alcohol had been eliminated while the alcohol tolerance emained much the same Five drugs were tested two hypnotics, pentobarbital sodium (Nembutal) and hexobarbitone (Evipal), an anæsthetic, ether, an analgesic, amidopyrin, and a central stimulant (metrazol, leptazol or Cardiazol) The effect of the hypnotics was estimated by noting the sleeping time after a dose of 20 mg per kg body-weight, alcoholism reduced this from 31 to 18 min for pentobarbital, and from 11 2 to 6 5 min for hexobarbitone For ether the amount needed to produce loss of the righting reflex was the criterion, and this rose from 0 87 c cm per kg before alcoholism to 1 28 c cm afterwards Analgesia was measured by determining the threshold faradic stimulus which would produce a sharp inspiration, and this was estimated before and after the administration of 100 mg of amidopyrin per kg body weight, the rabbit reclining in a hammock the while Here alcoholism made no difference whatever to the action of the drug The reactions of the rabbits to intravenous leptazol were graded into five classes 1, slight quickening of respirations, 2, twitching of the nose and eyelids, 3 a characteristic posture, with the back up, the forelegs stiff, the toes spread out and the tail raised, 4, violent convulsions, and 5, death In about half of the animals 10 mg of the drug produced either reaction 3 or 4, and the average response was the same before and after the acquisition of alcohol tolerance It seems, then, that cross tolerance extends from alcohol to other drugs depressing the central nervous system but no further

CHARCOT-LEYDEN CRYSTALS

Curschmann's spirals and Charcot-Leyden crystals are known to everyone who has read about asthma and though the spirals are probably casts of the smaller bronchi the significance and nature of the crystals is as mysterious as when they were first described in 1853 by Charcot in the heart-blood and spleen of a man who died of leukæmia Leyden saw them in asthmatic sputum twenty years later and since then they have been found in many conditions Speculation as to their nature has been common, coagulation or crystallisation products of eosinophils, spermine and calcium are among the substances said to be implicated It is certain, however, that these colourless, elongated octahedral crystals are most evident in diseases which cause an increase in the blood eosinophils Thompson and Paddock[1] have lately examined by wet smear the blood of 100 patients admitted to medical wards and suffering from a variety of illnesses without once finding the crystals, even though in some instances the eosinophils were as high as 25% Of 5 patients with bronchial asthma and an average eosinophilia of 8% none had crystals in the blood while one patient with chronic ulcerative colitis had typical crystals in the stools but none in the blood On the other hand 2 out of 3 patients with chronic myelogenous leukæmia, one patient presumed to have periarteritis nodosa and another with trichiniasis all showed numbers of crystals in wet-smear preparations Of 11 fatal cases of leukæmia, however only one had crystals in the tissues, these were present throughout the body but were most plentiful in the spleen and pancreas An attempt to induce crystal formation in guineapigs by inoculation with *Trichina spiralis*, which caused a 20% eosinophilia failed Thompson and Paddock are judiciously but regrettably silent about the nature of the crystals except that they are soluble in a variety of common chemical substances and that once destroyed they could not be reconstituted So far, therefore, all we can say is that Charcot Leyden crystals are most likely to be found in asthma, periarteritis nodosa, trichiniasis, in certain intestinal infections and in localised collections of eosinophils such as nasal polyps and skin blebs, the claims that they are present in prostatic secretions and in normal blood are probably false The feature common to these conditions is a high absolute or local eosinophilia and the association seems proven It is possible that the isolation and chemical analysis of the crystals would help in the understanding of the eosinophil

DRUGS AND DRUGGISTS

Addressing the Pharmaceutical Society on Jan 16 Mr Arthur Mortimer, secretary of the Wholesale Drug Trade Association, said that before the war started he had made a world survey of drugs in common use in Great Britain, with their countries of origin and alternative sources of supply This he had done in view of the possibility of interference, through any cause, with the normal supply of drugs The Association of British Chemical Manufacturers had also prepared lists of chemicals These investigations were followed by a census of the stocks of materia medica which had proved useful to the authorities The information thus made available was supplemented by an estimate of the volume of vegetable drugs and medicinal chemicals required by the health services, the Forces and the civil population in peace-time and an estimate of what might be required in time of war This work was not undertaken merely on account of fear of war but as a preliminary to ensuring the best use of resources and the encouragement of home trade Stocks

Annotations

RETIREMENT OF MR R H CURTIS

An outstanding figure in the public administration of this country has reached the end of his official life Mr Curtis, barrister at law chief officer of the mental hospital departments of the London County Council, has just retired under the age-limit after giving service for 46 years, first under the Metropolitan Asylums Board, then under the Asylums Committee, and since 1916 when their functions were transferred to it, under the L C C He will carry with him into retirement the good wishes and affection of all those who worked with him and whom he imbued with his own zeal He read widely and could argue medical points about the latest views on the treatment and care of mental patients with a wealth of knowledge which was often disconcerting He took a special interest in the pioneer work done at the Maudsley Hospital and in the research laboratories of his department He was proud of the two university chairs established at the hospital and the support accorded to it by the Rockefeller Foundation His official reports revealed his mastery of the English language and disclosed one of his hobbies which was the study of the meaning and derivation of words During the long evenings his active brain will need some occupation, and we commend to his attention the writing of a history of the Maudsley Hospital to enlighten future historians about the origin of this remarkable experiment in mental treatment

PSYCHOLOGY AIDING INDUSTRY

When war broke out it seemed possible that the activities of the National Institute of Industrial Psychology might have to be suspended but its work has gone on with a certain difference of objective The need of the moment is not so much the heightening of craftsmanship as the development of repetitive production As a peripatetic correspondent pointed out in October (p 499), craft cannot be acquired by drill but team work reinforced by motion-study and the discovery of the simplest and easiest way of getting results may become a very effective method of mass-production The demand for vocational guidance has not disappeared and an increasing number of industrial firms are turning to the institute for advice , indeed, with a staff depleted by the claims of the fighting services the institute is finding difficulty in meeting all the requests for help which are reaching it But for the most part the staff of the institute has been occupied in devising schemes for training operatives in engineering processes, electrical assembly work, power sewing machining and weaving , by introducing such schemes into industries they have shown that it is possible to shorten the normal period of instruction and ensure greater dexterity The training school is also used to separate those who are capable of doing skilled work from those who will be more successful in routine processes In one firm, where careful hand soldering of seams is required in the manufacture of air tight shell fuse cases, the weekly output at the start was only 1000 good cases and several thousand rejects , as skill improved an output of 10,000 good cases a week was achieved, and it seemed likely that this was the maximum to be hoped for When a systematic training scheme was instituted, however, the rejects declined and the good cases rose to 20,000 a week The institute has also been able to advise on hours of work, rest pauses, shifts, ventilation, lighting, light traps, and the colour of interior paint Help was given to the Joint War Organisation of the British Red Cross Society and the Order of St John of Jerusalem at a depot where parcels were packed for prisoners of war Simpler methods of packing and handling were advised, and improved equipment designed for a new depot Work for education authorities has gone on , intelligence and performance tests have been devised, and new tests for constructional abilities are being tried schools A vocational guidance experiment at Birm ham by Mrs E P Hunt and Mr Percival Smith, which the institute has been associated, show th children who were given—and took—vocational ad were placed more advantageously in industry than th who did not follow the advice , and also more favour than a control group who were given no advice

"CEREBRAL INFLUENZA"

G N Pattison[1] has described 20 consecutive ca what he calls cerebral influenza simulating early cere spinal meningitis arising in two nearby but entir separate military units The signs and symptom frontal headache, which was the most outstand feature, sudden pyrexia with slow subsidence, mal and general pains, an initial small petechial or scarlat form rash on head, neck and chest in 9 cases, photopho in some cases, and neck rigidity slight in 6 men a definite in one who also had a positive Kernig s One man was slightly delirious Lumbar punct seems to have been done in one case only, and th yielded a clear fluid, not under pressure and contain no organisms No involvement of the throat, no e chest was observed The duration of the illness is n stated, but it was short and recovery uneventful O about a third of the patients had chemotherapy a these did not recover so rapidly as the others, w were treated with aspirin, quinine and Dover's powd

It is a good thing to suspect cerebrospinal fever, a imperative to have a lumbar puncture done, in all febr conditions which resemble it and are otherwise une plained Points against the diagnosis of cerebrosp fever in Pattison's epidemic are the absence of vomitin of irritability on being touched or moved, of drowsin or prostration, of neck rigidity and Kernig's sign in t majority, the character of the rash, the clear cereb spinal fluid and the recovery without special treatme A scarlatiniform or *small* petechial rash on head, ne and chest does not suggest meningococcal so much streptococcal activity In meningococcal disease t rash may be macular or rose red papular at onset, b scarlatiniform or minute petechial rashes must be ve rare When the petechiæ appear they are nearly alwa irregular in size, and seldom minute, and their distri tion, unless very scanty, includes the flanks and upp thighs A clear cerebrospinal fluid may, of course, obtained in the septicæmic stage of the disease, b there is usually, though not always a slight increase cell content including polymorphs , and a few colon of meningococci are sometimes grown from clear flu with a normal cell count Rapid recovery witho serum treatment or chemotherapy occurs, too, in r mild or abortive cases, but is unthinkable in 20 conse tive cases A leucocyte count might also be of val In pure influenza the tendency is to a leucopenia w relative lymphocytosis, whereas in cerebrospinal fe there is constantly a decided leucocytosis

In the absence of further details it would be idle speculate on the real nature of Pattison's cases they occurred on the Mediterranean littoral the diagn might be anything from sandfly fever to prim smallpox in well vaccinated subjects It might even, the end, be necessary to relegate them to that hig popular category of the last war, P U O If th occurred in France or in this country a streptoco origin is not unlikely with a primary focus in a sinus elsewhere in the upper respiratory tract The r would appear only in a minority of the men who happened to be Dick positive reactors A scarlatiniform rash easily becomes a minute petechial rash in sites of pressure, like Pastia's sign in the flexures of the elbow in scarlet fever Slight neck rigidity is a subjective

Special Articles

MILY BUDGETS BY THE THOUSAND

SE interested in the nutiition of different sections population are used to collecting and studying al on what the people eat from a few score families ley do it very intensively, with trained workers to all the foodstuffs consumed by a household in a to measure the amount wasted, necessarily or essarily, and, in fact, to make quite sure that what usewife says fits in with exact observation Not households can be investigated in this detail or, l, would be likely to submit to the necessary entation To increase the field of observation a er approach must be adopted, and " what the r said " must be accepted, in this case, as evidence ier words, the housewife must agree to keep an nt of all her family's expenditure in a given week o keep it as accurately as possible This was the od adopted by the Ministry of Labour in its inquiry taken in 1937–38 into the customary expenditure orking-class households in Great Britain and iern Ireland, a preliminary account of which has een published [1]

e main purpose of the inquiry was the provision of for a revision of the cost-of-living index figures, i are still based upon the way in which the average y spent its income on different items in 1914 derable changes in modes of living and in the bution of expenditure have obviously taken place then, and the relative importance of the different , in the family budget, e g types of food, rent, fuel, ing, etc , was in urgent need of a re-assessment information collected is, however, of much interest any who are not perfectly at home with the construction of index numbers and not particularly interl in the finished product It gives a general picture e standard of living prevailing in this country in the war days and of what the people chose to eat in the lowly-paid majority of our population—not as exact cture, perhaps, as the nutritional worker demands erms of calories, protein, minerals and vitamins, a very valuable picture nevertheless

he present report shows the average amounts spent ifferent articles in 8905 families in each of which the l was engaged in an industrial, commercial or clerical ipation Each budget relates to 4 separate weeks ad over the year, to allow for seasonal variations ather larger amount of data is also given for each of 4 weeks, including families which supplied records 1 or more weeks but not for all four) In their graphical distribution they are representative of the ntry as a whole, but naturally they may be composed families with housewives more capable than the rage, for filling in forms is not everybody's strong it Certainly an average weekly expenditure of 5*s* per family seems surprisingly high in spite of the that the average composition of the families was 3 77 persons, of whom 1 75, or nearly half, were wage salary earners and only one was a child of under 14, per cent rented their houses and made an average kly payment for rent, rates and water of 10*s* 8*d* , per cent owned or were buying their dwellings and l corresponding charges of 12*s* 9*d* , 2 per cent , inly coalminers, lived rent free In total the average t of housing these industrial families was 10*s* 10*d* or irly 13 per cent of their total weekly expenditure of 5*s* (the actual amount was £4 6*s* 3*d* , but a slight justment has been made for expenditure on clothing ich appeared to be overstated) To clothing was otted a weekly average of 8*s* 1*d* , or between 9 and per cent of the total, to fuel and lighting 6*s* 5*d* , or o 8 per cent , to food 34*s* 1*d* , or approximately 40 per it , and to other items 25*s* 7*d* , or about 30 per cent attempt, it may be noted, was made to obtain the ual incomes received, for such might well have led to ack of cooperation

The proportion of expenditure devoted to food is nsiderably less than that shown in earlier studies, when has been nearer 60 per cent The smaller the income the more, of course, has to be allotted to food and with rising wage standards and less mouths to feed the more there is to be transferred to the large group of " other items "

These include cleaning materials 1*s* 1½*d* a week, household goods and utensils 1*s* 3¼*d* , furniture and carpets 1*s* 8¼*d* , tobacco and cigarettes 2*s* 6½*d* , travelling 2*s* 3*d* , newspapers, magazines and periodicals 1*s* , books and stationery only 2½*d* , postages 5*d* , cinemas 10¾*d* , other entertainments 5¾*d* , education 3¾*d* , hairdressing and shaving 6¼*d* , doctor, dentist, midwife and the like 10¾*d* , medicines, etc 6*d* , insurance contributions (state and private) 4*s* 5¼*d* , trade-union subscriptions 1*s* 4¼*d* , holidays 7¾*d* , beer, mineral waters, &c 9¼*d* (but possibly the average housewife has not full cognisance of this item) The contrasts speak for themselves and need no comment The distribution of the 34*s* 1*d* on food is also of much interest, and shows, with one or two exceptions, extremely little variability from one season of the year to another 3*s* 6¼*d* , or roughly 11 per cent , goes to bread and flour and as much as 1*s* 6¼*d* to cakes, buns, pastries, biscuits, etc On the other hand, oatmeal, rice, sago, tapioca, barley, macaroni, and breakfast cereals call for only 3¾*d* , there is clearly plenty of scope for response to the Minister of Food's appeal for a greater use of the first named article Meat (beef, veal, mutton, lamb and pork) calls for 4*s* 8¼*d* , a seventh of the food expenditure, and to this must be added 1*s* 6*d* on rabbits, poultry, sausages, &c , and 1*s* 11*d* on bacon, ham and gammon, a total of approximately 8*s* or nearly a quarter of the food expenditure on meat or meat products Fish of all kinds, on the other hand, amounts to only 1*s* 4¾*d* Fresh milk costs 3*s* 0¾*d* , giving the average family about ½ pint per head per day

In these happier days of peace margarine was in no great demand, for an average expenditure of 4¾*d* per week sufficed against 2*s* 5½*d* for butter Tea at 1*s* 7¾*d*. a week is a fairly heavy item and this average family consumes 1¼ lb of sugar per head per week at a household cost of 1*s* 0½*d* and rather more than 3½ lb of potatoes per head at a cost of 1*s* 1¼*d* Other vegetables cost 1*s* 4½*d* , apples, oranges and bananas 11¼*d* , other fruit (fresh, dried and canned) 10¼*d* , and eggs 1*s* 10½*d*

The precepts of the nutritional experts would suggest too great an attraction to meat, sugar, cakes and buns, too little to green vegetables, cheese and milk puddings. Even within the limits of expenditure possible the average diet could doubtless be improved The average, however, conceals as much as it tells How much variation is there between the diets of the population in different parts of the country, how do they compare between one level of expenditure and another, and how between the urban and rural worker ? The answers to these and many other questions the Ministry of Labour will be able to supply in time from the results of its large-scale inquiry Further instalments of this excellent serial will be looked for eagerly

---

MEDICINE AND THE LAW

Uncertainties of a Charitable Bequest

BECAUSE the law does not allow a bequest for " charitable or benevolent " objects to be a valid charitable bequest, some 140 institutions of a charitable nature may have to hand back sums amounting in all to more than a quarter of a million pounds In many cases the money has been spent and no funds are available for replacing it We have been taught to revere the certainty of the law and to admire the principle of judicial consistency We have understood that the law exists in order to protect acquired rights Unfortunately the whole law of charities is full of uncertainty, and, it now appears, institutions which have in good faith received money which the donor intended them to receive must attempt what may be the impossible task of repayment Guy's Hospital was given £20,000 with a request that it be specially used for a children's ward The Westminster Hospital was given £4000 which, it is understood, has been spent to excellent purpose The Royal National Orthopædic Hospital was given £5000 which was devoted to building a swimming-pool for the treatment of paralysis The diocesan board of Chichester received £2000 These benefits cannot be handed back in the form into which the money has been converted If the cash must be found, whence is it to come ?

Ministry of Labour Gazette, December, 1940 H M Stat Office, 6d in short supply were increased, fine chemicals which had not been made hitherto in this country were investigated and plant and working formulæ were devised. Mr. Mortimer referred to a number of crude drugs which are or may be in short supply, although, he added, "if care is exercised, and substitutes prescribed wherever possible, we shall have no difficulty in meeting the situation." Gentian, squill, liquorice, senega, cassia, belladonna, hyoscyamus, stramonium and colchicum should be available, in quantities sufficient to meet all ordinary needs, as a result of measures which had been taken to ensure supplies. Foreign owned British patents had proved a serious handicap to British manufacturers, but medicinal products covered by these patents were now being produced in this country under licences granted by the comptroller of patents and presented under trade names other than those used by the foreign owners of the trade marks. "There is," he said, "no call upon us as Britons to perpetuate the goodwill in enemy trade names, and a strong appeal is being made that the official names should be used wherever possible in preference to proprietary names in scientific literature, by manufacturers and prescribers, and in the teaching hospitals and institutions." The reference was particularly to those synthetic products which are the subject of monographs in the third addendum to the B.P. and he added that the Government naturally expected that every pharmacist would refuse to help to keep enemy trade marks warm. Mr. Mortimer ended with an appeal to set up an advisory committee for the drug trade.

FRIEDLANDER PNEUMONIA

Friedlander's bacillus, a short thick gram negative capsulated bacillus, has long enjoyed a reputation for causing a very severe form of pneumonia, and the tendency of older physicians to exaggerate the frequency of Friedlander pneumonia may be traced to Friedlander's early mistake in confusing his bacillus with the pneumococcus—which incidentally he, not Frankel, first isolated from cases of pneumonia. Bacteriological studies in large series of pneumonias put the incidence of Friedlander infections at 0·5–1%, although occasionally higher and even epidemic incidence has been reported. While the onset resembles that of a pneumococcal lobar pneumonia, certain clinical features help to distinguish Friedlander pneumonia which attacks mostly men in the older age groups. Hæmoptysis may be an initial sign, and the sputum is characteristically gelatinous and tenacious, and often brick-red in contrast to the rusty spit of the pneumococcal infection. Temperature is not high as a rule, the patient quickly becomes very ill, and the physical signs of a pneumonia, particularly crepitations and bronchial breathing, are often absent. There may be leucopenia or only slight leucocytosis. The diagnosis is made by bacteriological examination of the sputum. A gram stained smear shows many typical gram negative bacilli with a negative halo representing the capsule; mouse inoculation gives a pure culture of the Friedländer bacillus. The fatality rate of this acute and usually rapidly fatal infection is 70–90%. Besides this fulminating pneumonia a more chronic form occurs either as a sequel to the acute disease or ushered in by an acute phase, and Solomon[1] has lately recorded the clinical features in 17 cases of which only 4 died. One of the commonest complications of the acute disease is a non putrid necrosis of the lung; the resulting cavitation, usually in the upper lobes, is the outstanding feature of the chronic infection, and has led in a proportion of cases to a diagnosis of chronic pulmonary tuberculosis. The sputum is sometimes blood stained, but more often is rather copious, purulent and brownish yellow, but not foul smelling unless secondary infection occurs. The diagnosis is again confirmed by bacteriological examination of the sputum from which Friedlander's bacillus can be isolated though it may be in mixed culture; the same organism may, of course, be present in sputum apart from a pneumonic infection, as it is often associated with chronic sinusitis. Lung abscess is the most common complication of chronic Friedlander pneumonia and is sometimes accompanied by an encapsuled empyema. Pleural effusion, pulmonary fibrosis and delayed resolution are other complications. Treatment is mostly symptomatic, although Solomon on the basis of 4 treated cases thinks that sulphapyridine is likely to be useful in tiding the patient over the acute phase of the infection though not in preventing complications. He advises against surgical drainage of lung abscess, for this drains adequately through the bronchus. This chronic disease may last with intermittent pyrexia for months and even years.

TRANSPLANTED CHILDREN

WE are between the devil and the deep sea when we try to spare children the strain of war. To see children taken underground at six in the evening in a large city and kept there, exposed to infection, cramped for space to play, breathing fœtid air, disturbed by the pressure of adult life around them, is to appreciate fully the value of evacuation. To conduct a child guidance clinic in a reception area is, it seems, to see the other side of the penny. Speakers at the Tavistock Clinic (p. 121) tell that some children carry into the country the fear provoked by bombing, some break down as a result of their uprooting, some because they are placed in uncongenial homes and some from guilt at leaving their parents behind in danger. The position is not a simple one: there is evidently no clear right or wrong about evacuation and we must try to consider what is best for the greatest number. It is probably out of the question, in large schemes, to consider each case on its merits. Miss W. T. Alcock working in an eastern rural reception area speaks of the impact of "15 000 city-bred evacuees" on foster mothers, and the repercussions on the children, among whom 420 cases of breakdown had occurred. This gives an incidence of 2·8%, and it would be interesting to know how this compares with the incidence of breakdown among town children in times of peace. Many speakers testified to the fact that children stand up to the strain of actual bombing well; Dr. R. P. Garrow found that during 16 months in a population of 12,000–15,000 children in a heavily bombed area none had be alleged to suffer from strain, and this may well ha given an accurate picture of the situation. But must not lose sight of the fact that however well adapt a child may be to stand up to the strain of bombing, he totally unadapted to stand up to a bomb. Duri December 521 children were killed in air-raids, and it fair to assume that most of these deaths occurred towns. If those children had gone to the receptio areas, at least 500 of them would be alive to-day and of those about 15 would have broken down fro emotional strain. Even the unlucky ones might hav preferred the rôle of live dog to that of dead ho It must be remembered, too, that a proportion of th evacuated children referred to child guidance clin would probably have shown symptoms at home in tim of peace; and that among the large numbers of childre who have settled down reasonably well there are prob ably some who have benefited emotionally by evacuatio and have thus been spared a breakdown. The gain t children in physical health as a result of country life reported on all sides and is not lightly to be discounte This is not to pretend that children do not suffer fro transplanting, or that they do not experience emotion stress as a result of separation from their parent But the evidence suggests that by far the greater numbe of them adapt themselves to the new life, that they profi physically and that they are exposed to less direct risk o death. The position is not ideal, it has its own dangers but for the moment it is probably the best we can do.

Special Articles

FAMILY BUDGETS BY THE THOUSAND

Those interested in the nutrition of different sections of the population are used to collecting and studying material on what the people eat from a few score families And they do it very intensively, with trained workers to weigh all the foodstuffs consumed by a household in a week, to measure the amount wasted, necessarily or unnecessarily, and, in fact, to make quite sure that what the housewife says fits in with exact observation Not many households can be investigated in this detail or, indeed, would be likely to submit to the necessary regimentation To increase the field of observation a broader approach must be adopted, and " what the soldier said " must be accepted, in this case, as evidence In other words, the housewife must agree to keep an account of all her family's expenditure in a given week and to keep it as accurately as possible This was the method adopted by the Ministry of Labour in its inquiry undertaken in 1937–38 into the customary expenditure of working-class households in Great Britain and Northern Ireland a preliminary account of which has just been published [1]

The main purpose of the inquiry was the provision of data for a revision of the cost-of-living index figures, which are still based upon the way in which the average family spent its income on different items in 1914 Considerable changes in modes of living and in the distribution of expenditure have obviously taken place since then, and the relative importance of the different items in the family budget e g types of food, rent fuel, clothing, etc , was in urgent need of a re-assessment The information collected is however, of much interest to many who are not perfectly at home with the construction of index numbers and not particularly interested in the finished product It gives a general picture of the standard of living prevailing in this country in the pre-war days and of what the people chose to eat in the more lowly-paid majority of our population—not as exact a picture, perhaps, as the nutritional worker demands in terms of calories, protein, minerals and vitamins, but a very valuable picture nevertheless

The present report shows the average amounts spent on different articles in 8905 families in each of which the head was engaged in an industrial, commercial or clerical occupation Each budget relates to 4 separate weeks spread over the year, to allow for seasonal variations (a rather larger amount of data is also given for each of the 4 weeks, including families which supplied records for 1 or more weeks but not for all four) In their geographical distribution they are representative of the country as a whole, but naturally they may be composed of families with housewives more capable than the average, for filling in forms is not everybody's strong point Certainly an average weekly expenditure of £4 5s per family seems surprisingly high in spite of the fact that the average composition of the families was only 3 77 persons, of whom 1 75, or nearly half were wage or salary earners and only one was a child of under 14, 80 per cent rented their houses and made an average weekly payment for rent rates and water of 10s 8d , 18 per cent owned or were buying their dwellings and had corresponding charges of 12s 9d , 2 per cent , mainly coalminers, lived rent free In total the average cost of housing these industrial families was 10s 10d or nearly 13 per cent of their total weekly expenditure of £4 5s (the actual amount was £4 6s 3d , but a slight adjustment has been made for expenditure on clothing which appeared to be overstated) To clothing was allotted a weekly average of 8s 1d , or between 9 and 10 per cent of the total, to fuel and lighting 6s 5d or 7 to 8 per cent , to food 34s 1d or approximately 40 per cent and to other items 25s 7d , or about 30 per cent No attempt, it may be noted was made to obtain the actual incomes received, for such might well have led to a lack of coöperation

The proportion of expenditure devoted to food is considerably less than that shown in earlier studies, when it has been nearer 60 per cent The smaller the income the more, of course, has to be allotted to food and with rising wage standards and less mouths to feed the more there is to be transferred to the large group of " other items "

These include cleaning materials 1s 1½d a week, household goods and utensils 1s 3¼d , furniture and carpets 1s 8¼d , tobacco and cigarettes 2s 6½d , travelling 2s 3d , newspapers, magazines and periodicals 1s , books and stationery only 2½d , postages 5d , cinemas 10¾d , other entertainments 5¾d , education 3¾d , hairdressing and shaving 6¼d , doctor, dentist, midwife and the like 10¾d , medicines, etc 6d , insurance contributions (state and private) 4s 5¼d , trade-union subscriptions 1s 4¼d , holidays 7¾d , beer, mineral waters, &c 9¼d (but possibly the average housewife has not full cognisance of this item) The contrasts speak for themselves and need no comment The distribution of the 34s 1d on food is also of much interest, and shows, with one or two exceptions, extremely little variability from one season of the year to another 3s 6¼d , or roughly 11 per cent , goes to bread and flour and as much as 1s 6¼d to cakes, buns, pastries, biscuits, etc On the other hand, oatmeal, rice, sago, tapioca, barley, macaroni, and breakfast cereals call for only 3¾d , there is clearly plenty of scope for response to the Minister of Food's appeal for a greater use of the first named article Meat (beef, veal, mutton, lamb and pork) calls for 4s 8¼d , a seventh of the food expenditure, and to this must be added 1s 6d on rabbits, poultry, sausages, &c , and 1s 11d on bacon, ham and gammon, a total of approximately 8s or nearly a quarter of the food expenditure on meat or meat products Fish of all kinds, on the other hand, amounts to only 1s 4¾d Fresh milk costs 3s 0¾d , giving the average family about ½ pint per head per day

In these happier days of peace margarine was in no great demand, for an average expenditure of 4¾d per week sufficed against 2s 5½d for butter Tea at 1s 7¾d. a week is a fairly heavy item and this average family consumes 1¼ lb of sugar per head per week at a household cost of 1s 0½d and rather more than 3½ lb of potatoes per head at a cost of 1s 1¼d Other vegetables cost 1s 4½d , apples, oranges and bananas 11¼d , other fruit (fresh, dried and canned) 10¼d and eggs 1s 10½d

The precepts of the nutritional experts would suggest too great an attraction to meat, sugar, cakes and buns, too little to green vegetables, cheese and milk puddings Even within the limits of expenditure possible the average diet could doubtless be improved The average, however, conceals as much as it tells How much variation is there between the diets of the population in different parts of the country, how do they compare between one level of expenditure and another, and how between the urban and rural worker ? The answers to these and many other questions the Ministry of Labour will be able to supply in time from the results of its large-scale inquiry Further instalments of this excellent serial will be looked for eagerly

MEDICINE AND THE LAW

Uncertainties of a Charitable Bequest

Because the law does not allow a bequest for " charitable or benevolent " objects to be a valid charitable bequest, some 140 institutions of a charitable nature may have to hand back sums amounting in all to more than a quarter of a million pounds In many cases the money has been spent and no funds are available for replacing it We have been taught to revere the certainty of the law and to admire the principle of judicial consistency We have understood that the law exists in order to protect acquired rights Unfortunately the whole law of charities is full of uncertainty, and it now appears, institutions which have in good faith received money which the donor intended them to receive must attempt what may be the impossible task of repayment Guy's Hospital was given £20,000 with a request that it be specially used for a children s ward The Westminster Hospital was given £4000 which it is understood has been spent to excellent purpose The Royal National Orthopædic Hospital was given £5000 which was devoted to building a swimming-pool for the treatment of paralysis The diocesan board of Chichester received £2000 These benefits cannot be handed back in the form into which the money has been converted If the cash must be found, whence is it to come ?

When Mr Caleb Diplock died in 1936, his executors found themselves with some £263,000 to dispose of to such charitable institutions or other "charitable or benevolent" objects in England as in their discretion they might select That word "or," it seems, is fatal Bequests for purposes which are described as "charitable or benevolent," "charitable or public," and "charitable or religious" have at various times been held not to be valid charitable gifts because of the difference between charity and benevolence and because of the indefiniteness which "or" introduces In the Diplock case Mr Justice Farwell managed to uphold the executors' distribution The overriding intention of Mr Diplock, he said, was to benefit objects which were charitable in the strict legal sense, the addition of "or benevolent" was not enough to control that overriding intention The Master of the Rolls felt that the meaning of "or" must be disjunctive, it was no good pretending that it meant "and" or "*id est*" The Attorney-General, who appears in cases about charities in order to protect the public interest, sided with the executors and argued that "benevolent" had nowadays become really co-extensive with "charitable" The Master of the Rolls rejected the suggestion The court spent hours examining the nature of a charity—a question largely dependent upon the preamble to a statute of 1601 the only part of the statute which survives Many previous decisions were examined A bequest for distributing the egregious works of the fanatical Joanna Southcott has been held valid, so has a bequest to encourage rifle-shooting, although a bequest to encourage cricket or football is not Is it not really time that the law of charities was simplified and modernised ? Apparently in drafting the Diplock will a precedent was copied from a well-known textbook for conveyancers Somehow "or" was written in mistake for "and" Mr Diplock was not anxious about the exact words, all he wanted was that the residue of his estate should be devoted to the charitable objects to which it has in fact been applied Instead of that, the Court of Appeal declares this part of his will to be invalid, and the residue must devolve as if he had died intestate And thus, as counsel remarked, the money goes to a second cousin in Australia whom the testator had never even seen The Master of the Rolls fortifies himself with the reflection that the court must not be tempted to diverge from the strict path of legal dogma by any consideration of the consequences of its decision

Meanwhile what are the hospitals and other bodies to do ? Lord Justice Goddard suggested that this was a case for a private act There are plenty of precedents for private legislation to cure difficulties arising out of trusts and family settlements But this kind of retrospective intervention with rights of property is as unsatisfactory if effected by Parliament as when it is effected by judges Leave has been given in the Diplock case to appeal to the House of Lords But the bodies which in good faith accepted donations from the estate have now probably had enough of the law-courts for the present

FIRST-AID TEACHING

PROPOSAL FOR A TRAINING SCHOOL IN BIRMINGHAM

THE Joint Committee of the British Red Cross Society and the St John Ambulance Brigade in Birmingham believe that in the interests of first-aid training a civilian school on a national basis should be instituted In March, 1940, they appointed a subcommittee "to investigate and report upon the present methods of training first-aid workers"—a committee with a distinguished personnel including professors, physicians, surgeons and experts on first-aid training These agreed on the important principle that the rank and file of the first-aid services have often been taught too much, and that the aim should be to make teaching simpler but more thorough On the basis of the subcommittee's report the joint committee has drawn up a scheme for a civilian first-aid training school to be established in Birmingham The plan is suspended at present, because the central Red Cross and St John authorities in London would not give it their sanction, but it is a step in the right direction that the Queen's Hospital, shortly to become the Birmingham Accident Hospital, is to undertake the training of industrial workers in first-aid

The school would be intended primarily for laymen and its certificate would ensure that the holder possessed specialised training in the subject and that he would be capable of imparting his knowledge to others A body of lay instructors would thus be created who would be capable of improving the general standard of first-aid training throughout the country Those holding the certificate of the school would be invaluable to the commandants of British Red Cross and St John Ambulance detachments A R P authorities would welcome trained first-aid teachers and so would the police and fire brigades, school teachers could be offered a course suitable to their needs in training children, nurses, few of whom are taught first-aid at present, would find the course useful, and the scheme has the support of the Royal College of Nursing Industries, to comply with the Factories Act, must have a person "trained in first-aid" in charge of the first-aid arrangements, and the school would be able to provide courses suited to the special requirements and hazards of industry Doctors and medical students might also derive advantage from studying the methods and scope of first-aid teaching at the school

Particular attention would be given to practical instruction, the planning of tactical exercises, and—since the main function of the school would be to produce instructors—to teaching methods The cooperation of hospital and university staffs would enable students to gain authentic practical experience in casualty departments, operating theatres and at post-mortem examinations Lack of such opportunities is one of the chief drawbacks of first-aid as taught at present A real broken limb bears little relation to the obliging pantomime of a partner taking his turn at being the patient Some industrial employers are willing, moreover, to open their ambulance-rooms and treatment stations for teaching purposes

Courses—The usual course would last a fortnight, following the successful practice at the Government A R P school at Falfield Students would be required to live in and certificates would be awarded on the results of an examination at the end of the course A part time course of a minimum of 80 hours' work, to be held on evenings and at week-ends, would be arranged for those unable to give their full time to the work Special courses would be arranged for industrial students and nurses, and refresher courses would be held, annually or biennially, lasting one or two days

The school would be under the charge of a commandant who would be a medical officer with experience of teaching methods and there would be whole time lay instructors to assist with practical training, lectures and demonstrations would also be given by medical practitioners with special knowledge of different aspects of the subject For example, anatomy and physiology would be taught by a member of the university teaching staff, and first-aid in industrial poisoning by doctors with special experience of industry The better informed the instructor the more clearly he can distinguish what is, and what is not, essential knowledge for the student As the subcommittee pointed out, the focus of first-aid as taught today is the treatment of fractures and the accompanying splints and bandages But patients die, not from fractures, but from hæmorrhage, shock or asphyxia The best first-aid treatment is to leave a fracture alone or at all events to subject it to the minimum of manipulation The instructor must know all about splints, the more the better, but he must use his knowledge to explain their limitations in first-aid treatment Successful first-aid depends upon knowledge of what to leave alone

The school would be under the joint jurisdiction of the British Red Cross Society and the St John Ambulance Brigade in Birmingham, and governed by a board drawn from these two bodies, from the Ministry of Health, the medical faculty of Birmingham University, the British Medical Association, and from industry Candidates would be admitted on the recommendations of local authorities, industrial bodies, and the Red Cross and St John organisations There would probably be an inclusive fee of £8 for the full course of 14 days, with board, lodging, tuition and examination, and a fee of £4 for the part-time non-resident course of 80 hours

WAR STRAIN IN CHILDREN

A DEBATE AT THE TAVISTOCK CLINIC

CONTINUING the Sunday afternoon discussions (*Lancet*, 1940, 2, 818) at a meeting on Jan. 12, Dr. W. J. T. KIMBER being in the chair, Miss A. T. ALCOCK (play therapist) opened with the remark that after the last war children grew up under strain with resulting catastrophe. This war added to war strain the problem of separation from home and from the protection of its authority, and the threat to mental health was a serious one. She worked in an eastern rural reception area and all cases of difficult behaviour were referred to her department. The impact of 15 000 city-bred evacuees had produced emotional disturbances among foster-mothers, which had often precipitated breakdown in children rendered susceptible by their own prolonged psychic strain. The chief precipitating factors were uprooting from home, insecurity of the new environment, transferred adult strain and direct air-raid experience. Symptoms produced by bombing were easy to clear up; those due to separation were much more difficult. Four hundred and twenty cases of breakdown had occurred, 249 boys and 171 girls. 89% attended elementary schools and most of them were between 7½ and 11½ years old. This was rather surprising, as emotional tension was supposed to be at its lowest at that age. Nearly all were unaccompanied by the mother. The psychosomatic group contained 129 cases—more than a third of the whole. Psychoneurotic and behaviour disorders represented a quarter each of the total, and educational difficulties one-sixth. The first group included enuresis, incontinence, hysterical vomiting, somnambulism, fits and tics. In the early days children had been referred to the centre according to their nuisance value and enuresis had topped the list. Later, however, foster-mothers and local authorities became more sympathetic, and the effects of prolonged strain combined with this to make psychoneurotic cases the most numerous. The anxiety-depression figure was now the highest of all.

About 100 cases of enuresis had been sent up and some 500 more had been dealt with in the foster homes. Belladonna had seldom been successful but many responded to simple suggestion, relieving immediate anxiety and encouraging the child to believe that he would manage to control his sphincter. The fear of loss of control was so fundamental that it had seemed worth while to focus suggestion on that point. Glucose had been helpful. Separation from the mother had clearly been a factor, and foster-mothers who showed maternal tenderness were often successful where skill and cold kindness failed. A nursery school had been notoriously "wet" for a year under three successive matrons but under a fourth, who was much more maternal, it had "gone dry" in three months. The astonishing thing about enuresis was the measures that cured it: one foster-mother had cured it "with one look" and another by taking the child to the pigsty and saying, "Look at the old sow now; she's clean she is; she wouldn't wet 'er straw she wouldn't, and no more must you!" The resentment and anger of foster-parents put a great strain on the child. Many child-guidance workers had wrongly laid emphasis on the child's inability to help wetting the bed, without laying equal stress on the help that would be given to him. Often a child would say with stolid helplessness "Doctor says I can't help it." In some cases laziness did play a part. A child had been overheard to say to a companion, "It's horrid cold to get out—and they say I can't help it."

There had been twelve cases of fæcal incontinence, which seemed associated with a harsh foster-parent. The psychoneurotic group included 39 anxiety cases, 40 depressions, 4 of general nervousness, 2 hysterics and 2 obsessionals. Sometimes the symptoms on arrival from a bombed area, were really acute for a few days. One child had presented the complete picture of an adult depressive psychosis for nearly seven weeks; she had been a lively, happy child at home. One obsessional girl had compulsively hidden her clothes at night with amnesia in the morning; her phantasy had been of a baby her mother was supposed to be producing at home. She had been helped by encouraging her to mother the foster-mother's baby.

Treatment had been mostly environmental, directed to increasing tolerance and understanding in the foster-mother and to getting the child interested in local activity. Direct treatment had been to try and release emotional strain and get the child to talk about parents and family. There was often guilt at leaving the parent. Very few sedatives had been given; bromides had proved depressing but allonal had been useful. Children for whom physical danger had been the chief strain seemed to react by difficult behaviour, whereas those who suffered more from separation seemed to react with psychosomatic or psychoneurotic disorders. Behaviour troubles had been dealt with by providing suitable activities. Not more than one in fifty of the children had been in the same billet throughout the war, and the varying social standards and the divided loyalty between home and foster-parents made life very difficult for the children. School classes were composed of children who did not know each other or the teacher. Some children seemed to be ineducable, though not defective; they were quite unable to concentrate, with special trouble in auditory association.

In face of constant difficulty and danger there seemed to be a tendency to regress to an earlier stage of development. The strain could not be prevented but it could be countered and, if tackled in the early stages, could be cleared up without difficulty. Unfortunately public opinion was not adequately alive to the urgent national necessity of safeguarding the mental health of the children on whom would fall the burden of building the brave new world. If the result of this neglect proved to be deficiency or neurosis on a large scale, we should win the war only to lose it at home.

The CHAIRMAN said he had been struck by the effect on children of the threat to the parents left behind and the feeling of guilt in having "run away." It was vague, but very real, even in tiny children and produced continuous anxiety. Children were much less affected by bombing than had been anticipated. He thought that perhaps the type of child who reacted psychoneurotically made good at first and only broke down later, and that this might partly explain their rarity at the clinic in the early months. Was the lack of control in the enuretic child a retort to the lack of control in the home and nation? He thought that more than one in fifty of the children in his area stayed in the same billet. The feeling of isolation was a very important and inadequately recognised problem; to find them some constructive job was most valuable.

Dr. EVELYN LUCAS mentioned the enormous numbers of children suffering from neurotic manifestations during what was usually regarded as the "latency" period. It made her wonder whether children during this period at home did more than develop an adaptation due to repression, and so not adequate to deal with upheavals. The incidence of enuresis in Miss Alcock's area seemed to be small in proportion to the total number of evacuees. She agreed that it was important not to over-emphasise the child's inability to help it. One inveterate bed-wetter aged five had been brought up by very gentle, loving parents with whom she had an excellent relationship. One day the mother said "Well really I don't know what to do." "Well," replied the child, "all I can see is that you'll have to be firm with me!" It had then been mutually agreed that she should be smacked every morning after a wetting, and she had been completely cured in a fortnight. The majority of children who were neurotic were children whose consciences were plaguing them. The children she herself had seen in London had not shown the slightest sign of neurotic reaction to bombing; like adults, the more neurotic they had been before the less they were affected. It was not the external reality that affected them, but the fear of the revengeful attacks on the parents which they had secretly so often wished. War was a peg to hang neurosis on. There were undoubtedly children who did very well physically in their evacuation areas, but there were also many who were suffering severely from the mental strain imposed on them, and it was important to ask what could be done to help them.

Miss Alcock replied that the latency period was one when much was asked of children , the children in infant school were really babies, and when they moved up they had to be boys and girls Also, there were likely to be babies growing up at home, and these often stayed with the mother while the 8-year-old was evacuated The first need was for someone to make contact with local authorities and to “ spot ” these cases in the schools Direct psychiatric help was badly needed Regular play centres were required, so that sources of help were available The absorption of the children into local activities was of the utmost importance London schoolchildren in the country showed a very much higher immunity to colds and influenza than country children, but were very susceptible to skin diseases, showing an even higher incidence than in London , perhaps there was a psychogenic factor in this

Mrs Hamlin (social worker at the clinic) said that the children had stood up to the war situation very well , the cases were similar to pre-war ones and the history always went back before the war—with the exception of one somnambulist The absence of the father or brother on war service had been an aggravating factor Enuresis had been the chief problem, and there had been a number of general delinquency cases of the truancy type—due to lack of educational and amusement facilities Old patients, followed up after pre-war treatment, had improved remarkably since the war began On the other hand, a certain number of adolescents had not shown this improvement

Dr Lina Potter said that in the tube station to which she was medical officer, the children were not in the least afraid and were in excellent health Dr D W Winnicott thought that enuresis was often a valuable test to the child “ Am I loved when I'm naughty ? ” In his experience there was a relationship between incontinence and truancy Melanie Klein only permitted her pupils to do “ latency ” cases after they had worked with younger children and adolescents , she found latency a very delicate and difficult state Being at war was one thing and had an effect quite different from being in an air-raid, and that again was quite different from being bombed, being hurt and so on , and each aspect picked out a different type of child,

Dr R P Garrow said that the evacuated child was certainly worse off than the child left in London Medical officers of health had just received a regulation requiring medical examination of children thought to be suffering or likely to suffer in mind or body from remaining in the evacuation area In an indiscriminately bombed area to which he referred, hundreds of children had been exposed to bombs and had come through with no apparent sign of reaction During sixteen months, in a population of 12 to 15 thousand children, no child had been alleged to be suffering from such strain No-one but parents or teacher would report such a child, and if the parents reported it there would be no call for the “ compulsory evacuation ” envisaged by the order He would like help in interpreting the phrases “ suffering in mind or body ” and “ in a state of health such that it is likely to suffer ”

Dr Lucas asked if the order could be applied so that children might be sent back to London from the evacuation areas because they were suffering in mind through evacuation

Colonel J R Rees thought rough compulsory methods might work with adult enuretics but not with children Success was claimed in Northern Ireland by telling patients to go to bed saying over to themselves, “ My bladder is getting larger and larger and larger and larger ” Would these children be better in London ? in special schools ? in camps ? with their own teachers ? In the army there was infinitely more neurosis than among the civil population , the civilians had responsibility and a job, the good soldier was an obedient child and gave up all his individuality Should the children all be occupied in something of national importance ? Would that in the long run be the surest way of avoiding neurotic trouble ?

Miss G E Chesters (play therapist) suggested that play groups should be organised in reception areas The staff of day nurseries was apt to diminish for various reasons, and the numbers should be carefully watched Miss Alcock thought that country life provided adequate material to give children a play outlet

In England Now

A Running Commentary by Peripatetic Corresponden

My friend the shelter nurse took me through t snowy East-end streets to the riverside House af house showed empty gaping windows, beams fall awry, doors swinging loose or barred , here and ther little shop was still selling papers or a few sweets, a proclaiming against the evidence “ Business as usua She said that this street went on such a night, and th was where one fell, but nobody was killed—luck wasn't it ?—and led me in through a broken doorway show me the little house she had got her eye on for af the war, a shell now, but I could see it clothing its before her mind's eye In the end we came to shelter under a wharf and down we went The struck warm and stuffy in the doorway, partly with t human smell which takes a bit of getting used to, a partly with the dry hairy smell of Government canv nailed to bunks The nurse was greeted on all sides , was before six o'clock but people were settling in, a there were children everywhere “ Sickening, it is,” s said, “ they ought to be evacuated We had hardly a when Malcolm came ” (she was speaking of an offic tour of inspection) “ but a week after I couldn't ma out where they were all coming from Then I realise Christmas, of course They'd got them home f Christmas and they haven't sent them back ” threaded our way through the three-decker bunks rou which the children were playing tag The parents we laying out bedding, gossiping or sitting down to kn They were cheerful enough and took it all as a matter course Surely man is the most easily condition animal of any ? The medical-aid post was tucked aw in a corner, a tiny room separated into two by a partitio The outer part held two narrow beds already made up “ our clean sheets,” said the nurse with pride—a wir netting stretcher, a table and a row of chairs “ We ha gargling,” the nurse said, “ for the children , then I ca keep my eye on them And I get the P S Us to sho them how ” “ P S U ?” “ Pacifist Service Uni they do an awful lot for us Here's one of them ” H came out of the inner sanctum, looking about eightee but really twenty-two, and turned to at once as cour and lieutenant

I saw a lot of the P S U in the course of the evenin and thought them more impressive than most things t be seen about today The unit I visited lives in Stepney flat , there are ten young men, and two siste who cook for them They undertake every kind of usef job in the district—cleansing shelters, emptying latrine removing furniture free of cost for those who are bombe out, and carrying round cocoa and doughnuts to th shelters at night—rather guiltily because they think ought to be vegetable soup and raw carrots The spend a great deal of their time fixing up things for peopl who are puzzled—arranging matters with evacuatio authorities, putting in claims to the right funds for railwa fares or other allowances, and helping the rigid whee of local government to follow, in the main, the rig tracks They appeared to find the whole affair rathe entertaining, grinned about being sick the first time the “ did latting,” argued about world and local affai throughout their meals (accompanied by Mozart on th gramophone) and rushed off immediately afterwards o the next job They appeared to think nothing of th blitz, but mentioned the snowballing of the youth o Stepney with respect Occasionally a citizen in a shelte takes one of them aside “ I hope you won't tak offence at what I'm going to ask, Alec,” he begins— Gordon, or Charles, or whoever it may be—“ but is true that some of them chaps down at your unit conchies ? ” When told, yes, quite a lot of them, th citizen is nonplussed , his experience of the work of th unit strikes at his preconceived notions, so he shak his head a bit and gives it up

I was taken to dinner at the unit almost immediatel after arriving at the shelter, and then went out on cocoa round We picked up the cocoa at a place calle “ Paddy's Goose,” a social club with a canteen, and wer first to one of the archway shelters A railway bein lways a military objective the advantages of taking over under it are not striking but the arches were onvenient to brick in and local authorities decided to se them Condensation and water draining from the nes, used to trickle on the shelterers, but this has been vercome in some by building a wooden penthouse roof iside the arch with wood taken from demolished houses The wood is old knot-holed and worn and any bed bug ho has been bombed out would find in it a wide choice of onvenient well-built residences; those who have been here from the start are presumably at home and waiting o be shifted The P S U offered to creosote the whole nterior, but though the local body approached agreed hat that was the proper thing to do the final message hich came back was that the Government wouldn t ear of it: this ruling though fantastically improbable olds good and the authorities have compromised, in the rch I visited, by painting half the roof and parts of the osts which support it with cream paint The posts are estined to take bunks in due course which unlike the unks in most shelters will thus be fixed In view of his a suggestion was made that the lowest bunk should e rather higher than the regulation nine inches off the oor in order to make it easier to clean beneath it No he reply came back the Government wouldn t hear of it f there was any reason to suppose the Government was s sot in its ways as this the outlook would be black. he hitch is doubtless somewhere else in the machinery he lighting in this shelter was good there were two ianos and the people had made the floor into a vast and omfortable bedroom The bedding was spread on oards and boxes There were only half a dozen deck hairs in use Some of the children—there were fewer ere than in the first shelter—were tucked up already Others were playing an alarming game of getting the aby to jump off the piano into the arms of a slightly arger brother Cocoa went round Then three anxious-ooking young men came in from the Friends Ambulance Unit to show a film They conferred with the shelter marshal and with each other they chose a bit of wall hey ran up a silver screen about five foot by six in area, hey shone a beam upon it and instantly crocodiles and napping dogs appeared from busy juvenile fingers laced before the lens There was a little more fidget-ng and winding and then we found ourselves watching 'Rome Express.' and hearing the voices of the actors ooming unfamiliarly in the hollows of the arch We moved on and visited the crypt of a church very different rom the social centre we had left The people sat on wooden benches in cold and narrow passages they all eemed old and desolate, and the lighting was poor They had a medical-aid post, however, with a large and eassuring Irish first-aider in charge, and a cat who vanted to try the taste of Dettol In another railway rch there were as yet no bunks the brickwork had not been roofed in, and the beds were set round the walls voiding the places where the drips came in when it ained The company sat in a circle round a red-hot oke brazier and the atmosphere was tropical I went out anxiously trying to recall figures about carbon monoxide percentages Back we went through the snow o our first shelter Gargling was over and I had also missed baby bathing instituted by the nurse but there was a two-year-old in one of the beds considering whether to develop scarlet fever or not All was quiet bove and below ground We went into the inner room of the medical-aid post where there was a three-tier bunk, table, cupboards of official equipment, some chairs and primus stove which had already obliged by boiling the ettle for tea Then I met the shelter marshal and he ook me round now that everyone was abed and sleeping he shelter is a large one and the bunks are set close, e wriggled through passages between them The helter marshal, who felt he must do the honours for he shone his torch serially on "the fattest woman we ve ot," "husband and wife down below children up top" nd "our bad heart case' I felt apologetic at this nauthorised peep-show but the sleepers never stirred saw the latrines, chemical buckets with seats, just dequately screened with canvas and I saw the place where the new water-closets are being built at speed—he workmen were in at eight on Sunday morning The marshal was keen, proprietary and kind, he clearly felt was his shelter I reflected that the nurse had called it "my shelter, and the P S U referred to it as "one of ours' No doubt these sleepers felt it belonged to them and it was certainly theirs if numbers count And the local authority has an official claim

But it must be the universal feeling of ownership which makes this one of the good shelters and which will raise the standard in all shelters in time I went to bed at last in the bottom tier of the bunk in the medical-aid post and discovered a new and forcible objection to lying within nine inches of the floor, the insecticide with which the P S U in their cleansing operations liberally sprinkle all floor cracks is so powerful that I began to suspect myself of having insect blood But the bunk was comfortable and the Government blankets warm I went to sleep instead of dying In the morning when we went up blinking into the daylight, the wind off the river smelt strange We breakfasted with the P S U to the melodies of what one of them, contemplating the labours ahead, called "Eine kleine Latmusik

* * *

I wish I had a penny—tax-free, of course—for every time I have been to a pantomime As a boy a taste for low comedy and catchy airs often took me, with a fellow-addict to the gallery of the local theatre during the Christmas holidays Now, as befits a dutiful parent I have had to resume the practice But no longer do I frequent the gallery, instead I go once a year only and then affluently in the stalls This year the slapstick was well up to standard and I found myself waiting eagerly for the old jokes and laughing at them anew Once more I noted how the pantomime tradition permits the author to play fast and loose with the plot of the story and the satisfactory—not to say smug—way in which good triumphs over evil and right over might It is really deplorable how so many of us applaud the moral principle on paper without bothering a bit about it in fact Contrary to my experience of fairy queens who generally look obese and hypertensive, this year's model was I thought, a trifle on the pale side and looked as though she could have done with a course of Blaud's pill But it was heartening to see how we can laugh at our present misfortunes, the children especially being delighted with anachronistic references to sirens shelters and gas-masks As I grow older I find myself paying less attention to the players and more to the children in the auditorium How they do laugh to be sure, particularly at somebody s discomfiture The upsetting of the dame on her milking-stool by the comic cow was received with sheer and shrill ecstasy—even when it happened for the third time Next year I should like to sit at right angles to the stage in the gangway between the stalls and the pit so that I can really watch the audience without getting a wry neck

* * *

One night one end of the nurses home was wrecked by a bomb but happily they were all over at the hospital, most of them doing voluntary duty admitting casualties The next day one of them received a wire from her father in the country "Have heard the news pack everything and come home' She wired back "Nothing left to pack not coming"

* * *

A few days ago the *Times* on its middle page published a letter from an army officer of high rank in which he said "Our new armies are being officered by classes of society who are new to the job The middle. lower middle, and working classes are now receiving the King's commission These classes unlike the old aristocratic and feudal (almost) classes who led the old army, have never had 'their people' to consider They have never had anyone to think of but themselves This aspect of life is completely new to them, and they have very largely fallen down on it in their capacity as army officers These young officers have been reared in an atmosphere in which the State spoon-feeds everybody from cradle to grave and no-one feels any responsibility for his fellow men' This reactionary little swing with its implied boastfulness, is without doubt due to our successes in the Western desert Self-esteem is being restored, self-confidence is coming back, and must find expression if not by the sword then by the pen. The hackles are up the erectores pilorum prance, the adrenals swashbuckle the high gods in the cortex are ignored After Dunkirk it was a very different story We had been defeated, the nation was as one man, " one family " the *Times* told us, fear had made kindred of us all, protoplasm sought brother protoplasm, and we humbly felt the brotherhood of man But I think that the editor of the *Times*, or whoever is responsible for vetting their correspondence, should realise that the process that is so obviously gripping the Colonel has got its hold on the rest of the nation too, even including " the middle, lower middle and working classes " Anyhow Mr Priestley will put all that right next Sunday

Letters to the Editor

PREVENTION OF DIABETES

SIR,—Professor Himsworth (*Lancet*, Jan 4, p 24) states with regard to the data presented by Haist, Best and Campbell in the *New England Journal of Medicine* (1940, **223**, 607) that " far from indicating rest of the islet tissue the authors' data concerning the effects of starvation, high fat diets and excessive administration of insulin can be more easily interpreted to mean overstrain of that tissue " Part of the evidence in question comes from experiments in which dogs, made permanently diabetic by treatment with anterior pituitary extract, were fed on a diet of pure fat (beef suet) Mr H P Marks and myself (*J Endocrinol* 1939, **1**, 470) found that this procedure not only almost completely abolished glycosuria and ketonuria in such a dog, but increased the proportion of a test dose of glucose retained by the animal from 20% to 80% It does not seem possible that this increase in the sugar tolerance of the diabetic animal was brought about by an overstrain of its islets Perhaps I may quote our tentative explanation of these observations—" the pancreas of the pituitary-diabetic dog contains a small amount of insulin which, however, is required little, if at all, for the regulation of metabolism when a diet of pure fat is given This insulin therefore accumulates in the pancreas and is available to ensure the proper metabolism of at least a portion of a small dose of ingested carbohydrate, in spite of the fact that, in accordance with Himsworth's ideas, the insulin-sensitivity of the tissues may have been depressed by the high-fat diet " Himsworth's theory, that the sensitivity of the tissues to the action of insulin is diminished by a diet of fat, does not appear to be incompatible with the belief that the absence from the diet of sugar, or glucogenic substances, rests the insulin-secreting mechanism of the pancreas

Professor Himsworth also states that the views expressed by Professor Best and his colleagues, and their suggestions for medical treatment, do not depend on evidence tested in the clinic Discussion of the general sense of clinical evidence is beyond my proper scope, but I cannot refrain from quoting from the clinical investigations of Karl Petrén, which are not mentioned by Professor Best and his colleagues, and which indeed appear to have received too little notice generally " In grave diabetes, I have for some years past often used one, two or three successive days of a diet of only butter (about 100–200 g) " (*J metab Res* 1924, **5**, 34) In this paper Petrén gives numerous examples of the treatment of severe diabetes with a diet consisting almost completely of fat

DYSPEPTICS IN THE ARMY

SIR,—It would appear from your leading article of Jan 11 that the figures and conclusions of Mr R T Payne and Dr Charles Newman (*Brit med J* 1940, **2**, 819) are being accepted as the explanation of dyspepsia in the Army I have been astonished that so far no comment, critical or otherwise, has been made or at any rate published I find that the data in this article are almost wholly incomprehensible in relation to my own experience and that of other gastro-enterologists working in the Army with whom I have discussed them

We are asked to believe that nearly 90% of dyspepsia in the Army is due to peptic ulceration It may be that some authorities wish to believe that all dyspepsia in the Army is organic, and if so this article must indeed represent an almost complete wish fulfilment I believe that this is far from the truth Of 287 cases of dyspeps these authors found 226 " proved " ulcer cases (though i 8 the site was undetermined) and another 21 " probable ulcers, making a total of 247 ulcers out of 287 allege unselected cases of dyspepsia With the items liste under indefinite (4) and wrong diagnosis (11), carcinom volvulus and gastro-enteritis (7), I am not concerne but on the figures for gastritis and duodenitis (7) an neurotic and functional (11)—or say 3%—I should lik to make some comment

We are reminded in your leader that a soldier is onl a civilian dressed up in uniform Even in civilia hospital gastro-enterological practice, *not more than o in four cases* with dyspepsia as the presenting sympto are found to have organic disease , the rest are gastr neuroses What then has happened to these cases in th *Army ? What has happened to the small but qui* definite group of reflex dyspepsia, for example of gal bladder origin, the dyspepsia of early pulmonary tube culosis, that of faulty mastication, dental and mechanic origin, and of achlorhydric dyspepsia ? If the inciden of peptic ulcer is so high why have we not seen more cas of gastro-duodenal hæmorrhage and perforation ?

With such a high proportion of " proved " ulcers w are entitled to know the nature of the proof accepted b the authors in compiling their diagnostic tables In o line of the article they speak of exact diagnosis but in th *next state that radiography was often done too late t* reveal an ulcer crater It is possible that the fault diagnosis of peptic ulcer may be related to the type o X-ray plant available for use in the majority of bas hospitals which, in the hands of the most expert radiol ogist, may hardly be adequate for exact gastro duodena X-ray work , or it might be ascribed to the need fo entering an " exact " diagnosis before a case was evacu ated to the U K How many times has accuracy i diagnosis been sacrificed to the necessity of sayin " something definite " for the purpose of transfer an evacuation ? Yet these diagnoses must perforce be use by the medical disembarkation and distributing head quarters and provided the authors with their suspecte gastric and duodenal cases in the hospitals where they saw them Apart from diagnostic accuracy *this metho* of selection is surely unsatisfactory as a means of providin a fair sample of dyspepsia in the Army, although it i quoted as a representative and unselected sample o dyspeptic cases

Next we are asked to believe that only 3% of cases o dyspepsia are neurotic and functional My colleagues in psychological medicine do not usually lack the ability or courage to present their views in your columns Does their silence mean that they agree with this astonishing conclusion ? My interest is in organic medicine but in gastro-enterology it is impossible to ignore the part that psychological factors play in producing gastric symptoms My experience among army dyspeptics does not materially differ from that of civilian hospital and private practice My present figures indicate *that 60%* of army dyspeptics are fundamentally neurotic, the dyspepsia being either purely psychogenic or psychogenic factors being respon sible for a continuance of symptoms far beyond the " organic " span Even among cases with a past history suggestive of ulcer, or cases of proved ulcer, the perpetua tion of symptoms (despite full ulcer dietetic regime) when all possible complications of the " ulcer " have been excluded suggest that some of these patients show a psychological " pattern " reaction reproducing subcon sciously a syndrome which once may have had organic significance but is now purely psychogenic

Finally I have reason to doubt the view that cases of persistent dyspepsia probably have severe gastritis The appeal to direct inspection of the stomach by gastroscopy among 58 otherwise negative dyspeptics with persistent symptoms has shown that in two-thirds the mucosa wa normal, in one-fifth trivial to moderate superficial mucosa changes, for the most part capable of being satisfactorily treated, were present Only in about one-seventh were serious organic mucosal changes found, including acut ulcer missed by X ray, chronic patchy gastritis, anasto motic gastritis and atrophic gastritis

Unfortunately only a small number of these gastr neuroses show easily detectable evidence of neurot illness—e g , somatic symptoms, tremors, sweats, palpit tion, acknowledged anxiety, fears, extreme boredom ew are highly suggestible, while a still smaller number are frankly hysterical showing induced pseudo-epileptic rises, anæsthesias and the like Is it because the psychotherapeutic outlook for the neurotic dyspeptic is not very favourable that the problem has not gained more active attention from our colleagues in psychological medicine ?

Pinewood Berks STANLEY J HARTFALL

B M A MEDICAL PLANNING COMMISSION

SIR —You suggest in your last issue that the Medical Planning Commission set up by the B M A can properly laim to be representative May an old reader join issue with you on this point ? It is assuredly not representative of all those interested in the future of the medical services Perhaps it was never intended to be so, but to express only the views of the medical profession on its own future Is it even representative of the medical profession ? Where are the left-wing representatives whose influence might go some way to neutralise the almost overwhelming preponderance of those whose oyalties and already-announced policies tie them to the chariot wheels of the B M A ? It is surely mere affectation, for example, to suppose that the Medical Practitioners Union (which is already exploring similar ground) stands for nothing at all in the medical profession, or is incapable of contributing useful material to the commission's deliberations It is quite possible that the M P U. would decline to send representatives, but it should surely have been asked It may perhaps be doubted whether any body representative only of the medical profession, and excluding representatives of the Services, the Ministries and the M P U , can possibly hope to command any appreciable degree of public confidence

Sevenoaks GORDON WARD

SIR,—Your leading article of Jan 11 is timely Reference is made to the inexplicable secrecy in which the commission was established , and your criticism of the age-distribution amongst its personnel seems to be justified But what is most important is your opportune reference to the tendency which has undoubtedly existed for some time past for such bodies to regard themselves as more representative of the profession than they are , and to the undemocratic method of creating a finished scheme when the vast majority of the profession have not had any opportunity of expressing their approval or judgment on it This practice has caused anxiety in the minds of many members of the profession , an anxiety which has found expression in numerous letters published in the medical press during the past twelve months

The decision to create a commission to inquire into the present organisation of the medical profession is most wise , and no-one will doubt that the B M A possesses excellent constitutional advantages for appointing such a commission, and permitting it to function in the most efficient manner But there is evidence to show that executive bodies have tended to lose sight of their democratic constitution , and to complete far-reaching arrangements affecting in a most intimate manner every member of the profession without first acquainting them with the details of the scheme, and without giving the profession as a whole the opportunity to discuss, to consider, to sanction or to modify arrangements which when brought into operation may prove so detrimental to the profession's well-being and to the community The ever-increasing tendency to recognise more and more so called ancillary services has not met with the unanimous approval of all members The precedent thus created has already brought an ever-increasing number of requests from various bodies, whose formal recognition cannot ultimately be in the best interests of the profession or the general public Furthermore, since certain of these bodies have received formal recognition, there is already evidence of an abuse of privilege which cannot be controlled, since the General Medical Council has no jurisdiction over the offenders The ever-increasing number of foot doctors advertising in the public press is surely a testimony to this statement

But perhaps the most striking example is given in the manner by which the original Emergency Medical Service scheme was established Had the profession been given the opportunity of considering and discussing the details of this scheme, many of its gross absurdities, its injustices and its inherent weaknesses would have been pointed out and modified as the result of free debate and the knowledge of practical experience But no such opportunity was ever given The profession was asked to sign a form of registration in a purely voluntary capacity it was asked to elect local emergency war committees, the characteristics of which were predetermined , and it became more and more obvious that the voluntary form of registration would become a binding and compulsory force once a state of war existed Many individual medical men both consultants and general practitioners, have found themselves as a result in a position where their rights as individuals and their freedom as citizens, indeed the very financial security of their practices, have been swept away from them, leaving them stranded, and without any means of redress, justice or compensation The many cases of hardship now existing among all grades of the profession throughout the country as a direct consequence of the operation of the original E M S scheme stand as a certain indictment against the executive bodies responsible for these Star Chamber methods No-one will deny that during a state of national emergency hardships and sufferings are bound to occur , and every right-minded citizen is willing to take his fair share and to relieve as far as possible the misfortunes of his neighbours But the operation of the original E M S scheme made it impossible for mutual assistance to be given Membership of the Protection of Practices Scheme was not compulsory, and the sanction or the recommendation of a local medical war committee was necessary before the individual could do anything These hard-worked bodies must have found it extraordinarily difficult to cope with their duties, and although they have been much criticised they have functioned as satisfactorily as was possible under the circumstances Ultimately it was found expedient to revise the E M S scheme fundamentally in the light of practical experience , but not before irreparable damage had been done to the practices of many Would not free debate and discussion have prevented these adverse results ?

If the planning commission will seek to obtain evidence from all possible sources and will publish this evidence with its accompanying recommendations and report thereon in the recognised medical press , and if the results of its deliberations are made open to the profession for free debate and sanction, the commission will have fulfilled an excellent and most timely duty for which the personnel will receive the full gratitude of all But if the executive of the B M A , having received the report and recommendations of the planning commission, should draw up and commit the profession to any reorganisation, or to schemes of national service , if it should present to the rank and file a "fait accompli " and a request for signature in agreement, as happened in the case of the E M S , the executive will exceed the powers of its own constitution , and not only will it fail in its duty to the profession but it will also create a most difficult and undesirable schism Already another professional body has been circularising the profession with details of a proposed scheme of nationalisation This division of the profession into two rival camps is surely most undesirable at the present time , and if a further splitting up is to take place as the result of a strongly organised opposition to these undemocratic methods the end-result will be that the Government will step in and decide the issue once and for all A house divided against itself cannot stand

The coming of peace will not bring a solution to the many social and national difficulties of which mankind has now become conscious It is probably true to say that not since the Reformation have the peoples of Europe been so shaken by ideological differences, both national and human, political and civil, economic and financial These ideological differences have now reached such a degree that they have become blatant signs of gross disease in the civilised state of our western world Their interpretation and their appropriate treatment will require the concentrated efforts of all concerned under a patient, wise and philosophical leadership Nor is it possible to assess with any degree of accuracy how the requirements of the so-called "New Order" may best be fulfilled in so far as the medical profession is concerned in carrying out its duty to the community Nevertheless, it is obvious that the most careful and statesmanlike planning will be required if our traditions, our academic independence, our professional freedom, and above all our ethics, are to continue to exist, and to regain their erstwhile high standard No claim is made for a revival of altruism in our medical life But few will deny that, in company with other professions and callings, the heat of intense competition and the economic difficulties of modern life have brought about an unhealthy state in the general organisation of the medical profession, which manifests itself not only in the widespread apathy to these most important medico-political considerations but in the economic state of our voluntary hospitals, and in the very relationship between the profession and the community Is not the growth and development of quackery during recent years in itself an indictment against our profession ? A section of the community will always be thrilled by the jargon of the charlatan and flattered by the panderings to its pseudo-intellectualism , but the fact remains that if the profession as a whole satisfied the demands of the community as a whole quackery could not grow and thrive as it has done

At no time has the medical profession been in greater need of strong leadership than at present , strong statesmanlike *leadership to carry out much-needed reforms* , to enable the profession to assume its true relationship to the community and to the state without loss of that dignity, prestige and independence for which the many illustrious men of the past strove so hard to achieve and to hand on to us as an inheritance and trust

Bournemouth LLOYD OLVER

DIPHTHERIA PROPHYLAXIS

SIR,—Now that diphtheria prophylaxis has been taken up by the Government as a national measure it is obviously up to all local authorities, all educational authorities and all medical officers of health to endeavour to get as large a proportion of our child population immunised as possible in order to get the maximum beneficial effect from the measure It seems to be admitted that a half-hearted resort to this measure is likely to be useless, if not worse than useless For this reason Dr Benjafield's letter in your issue of Jan 11 is to be heartily welcomed But I would like here to make a practical suggestion to remedy a rather glaring anomaly —viz , that as immunisation is to be done chiefly through the schools, it should be done on the basis of attendance at a particular school, rather than on the basis of the child's residence in the area of a particular authority It frequently happens, especially in rural areas, that children residing in the area of one local authority may be attending a school situated in the area of another authority, and therefore are liable to be excluded when that particular school is being immunised This is a very short-sighted policy, and there is the less excuse for it now that the Government is providing toxoid free of charge Clearly, there should be a complete give and take between local authorities on this matter, and " Let them all come, the more the better " should be our motto

Leicester C KILLICK MILLARD

SAVING ON DRUGS

SIR,—In your leading article of Jan 4 you remark that *an insured person will not relish being refused his familiar* medicine while its proprietary counterpart can be bought at any chemist's shop Here you touch on a frailty common to all mankind, whether represented by insured persons or panel doctors if the goods are there some of the public will have them, and if the drugs are there the doctor will prescribe them The remedy is to cut off supplies of non-essential drugs, and then it will be as useless to try to buy or to prescribe them as to ask for an onion I cannot think that makers of proprietary medicines will be allowed first call on supplies while doctors, hospitals and dispensers go begging The revenue from patent medicines is too small to influence the Treasury

If the therapeutic requirements committee can do no more than advise I agree that much of its work will be wasted, but in fact it can do much more than that This committee seems to be in the position of an advisory body to a Government department We are bound to assume that if the Ministry of Health tells the appropri ministry that cargo space need not be used to br certain goods to this country the goods will not come, a the recommendations of the therapeutic requireme committee will then have the effect of a departmen order If the ministry which is advised by the co mittee acts on that advice the drugs on the non essent list will soon be as obsolete as the banana In any ca it seems fair to suppose that the committee which is compile a war formulary, on the initiative of the Minis of Health will ignore the existence *of those items* wh have been declared unnecessary Incidentally, it is to hoped that the Government will not use the power tha undoubtedly possesses under the Defence Regulations forbid the prescription of any drug not included in war formulary

The inclusion of the wholesale drug trade in the form lary committee implies that the availability of suppl will be kept in view by the committee during the wh of its work This is, of course, the crux of the matte if all drugs were freely available there would be no n for a book of emergency recipes

Let us hope that the formulary will not have to be use for long and that we shall soon be back to the B and the B P C which take ten years' labour to prod *instead of the " month or two " which you allot to* formulary committee If the war formulary can produced so speedily it will be because of the vast amo of work which has been done by the Pharmacopo Commission and the Pharmaceutical Society in prepa tion for the next issues of their respective volumes, wh cannot be published while the paper shortage lasts have had two important ad-hoc addenda to the B since the war began and others are probably in offing , this is a good record for a body which must mo cautiously Why you should suggest handing over responsibility for the B P to the Ministry of Health I to understand Why put old wine into new bottle Why make the tax-payer pay for a job which now co nothing, and the profits from which are spent on resea for future pharmacopœias ? Let us have the w formulary by all means, and quickly, but let us refra from trying to take long views while visibility is bad

Whitehall Place, S W 1 F C GOODALL

BREAD

SIR —The present controversy regarding the compo tion of bread prompts me to recall the experiences of last war when in the Mesopotamia campaign diseases d to vitamin deficiency were a serious problem These a fully dealt with in the articles on beri-beri and scurvy the Official History of the War (vol 1, Medical Servic Diseases of the War, vol 1, chaps 14 and 18), which was my privilege to write

Up to 1917 fresh foods were almost unobtainable a the importance of the composition of the flour becan enhanced The British troops were supplied wi bread and biscuits made from white flour and suffer from deficiency in the vitamin-B complex and the oth important accessories which are present in wholeme flour In consequence a number of cases of beri b occurred The Indian troops were supplied with wholemeal flour (atta) and also with dhall (a lentil) bo of which were rich in vitamin-B complex and the oth accessory *food factors in which white flour is* deficie Beri-beri did not occur in the Indian troops The r of beri-beri in British troops was obviated by the intr duction early in 1917 of the issue on three days a we of bread composed of a mixture of wholemeal a white flour , also Marmite, which contains yeast extra and is rich in the vitamin-B complex, was issued tw weekly There were no cases of beri-beri after adoption of these measures

It is now generally accepted that white bread and wh flour are greatly inferior to wholemeal bread and flour foods in a dietary where bread is the most importa basic constituent, which is the case in war-time owing unavoidable food shortage In this war the Governme have wisely decided that some action is necessary sin the nutrition of the nation is of paramount importance victory The suggestion has been made by the Minist of Food that the addition of synthetic vitamin B_1 a calcium carbonate to white flour would yield which would compare favourably with wholemeal bread On theoretical grounds there are serious defects in this proposition since vitamin B_1 does not supply the deficiencies of white flour in the vitamin-B complex, which includes many other vitamins than B_1 such as vitamin B_2 and B_6 Also the absence of vitamins A and E nicotinic acid and riboflavin in the reinforced white loaf and the eficiency of mineral salts and fat are of great importance

This criticism has been fully confirmed by Dr Harriette hick's research reported in THE LANCET of Oct 26 940 It was clearly proved by feeding experiments on oung growing rats that the reinforced loaf was inferior o the wholemeal loaf The inferiority was attributed to ick of B_2 vitamins

A solution of the present difficulty might be obtained s in Mesopotamia by the issue of bread composed of a ixture of white and wholemeal flour A loaf made om equal parts of each kind of flour would, in my pinion be much superior to the Ministry of Food einforced loaf since, among other advantages, it would ontain the vitamin-B_2 complex which is absent in the atter A loaf composed of 75% wholemeal and 25% hite flour would be still better and was shown in xperiments in Mesopotamia to be very palatable The erfect solution of the problem would be the universal se of a loaf composed of 100% wholemeal flour to which ublic opinion would soon be converted if the true facts ere fully understood The present stocks of white lour might be utilised by the provision of a mixed loaf, holemeal and white, as suggested

Wholemeal bread if properly baked has more flavour han white bread and there is no evidence that the mass f the people will not eat it It is important that the flour should be prepared so as to give a palatable and efficient product and that the baking process should be carefully regulated

The universal use of wholemeal bread is by no means an insuperable problem The education of public opinion, the coöperation of millers and bakers, and the application of experimental research so that efficiency may be ensured will do much to bring about this desirable reform The gain to the nation in improvement of health would be incalculable

London, W 1 WILLIAM WILLCOX.

MOSQUITOES INFESTING DEEP SHELTERS

SIR,—In your issue of Jan 4 Mr P G Shute described the infestation of deep shelters in London by the culicine mosquito *Culex molestus* May I point out that this mosquito was first located in Britain by Mr J Staley and myself in October 1934 when experimenting (at Hayling Island) with an egg-raft that we supposed to be of the ordinary domestic species *Culex pipiens* In the following year we obtained further specimens of *C molestus* both from eggs laid by a blood-gorged female caught in an hotel in Westminster and from larvæ collected in stagnant water adjacent to some mosquito-infested cottages in Hull

During the years 1938 and 1939 at the request of the entomological department of the Natural History Museum and with the coöperation of the London County Council, we extended our research to various Thames-side districts, notably Battersea, Bermondsey, Chelsea Deptford, Fulham Greenwich and Isleworth, in all of these districts many houses and institutions were found to be periodically invaded by hordes of fiercely-biting females of *C molestus* At the outbreak of war local authorities naturally diverted their attention to more important matters and these investigations were suspended

Both in the larval and adult forms *C molestus* and *C pipiens* resemble one another so closely that the presence of the former species in Britain was entirely overlooked up to November, 1934 The two species differ however in important respects *C molestus* is one of our worst biters whereas *C pipiens* rarely if ever attacks human beings its customary victims being birds Moreover, *C molestus* is both *stenogamous* and *autogenous* that is to say the adults will mate in a very small space (even in a test-tube) and the fertilised females are able to lay *some* eggs (about 70) without having had a preliminary meal of blood Of the 2000 odd species of mosquitoes known in the world only two besides *C molestus* have so far been found to be autogenous—namely the British species *Theobaldia subochrea* and the Australian species *Aedes concolor* Combining as it does the characteristics of stenogamy and autogeny *C molestus* is extremely easy to breed in small laboratory jars all the year round The methods of distinguishing *C molestus* and *C pipiens* from one another are fully described in my book "The British Mosquitoes" (British Museum, 1938) which was unfortunately in print before our Thames-side data were available for publication

In conclusion I may perhaps mention that the total number of British mosquitoes at present known is not 29 (as Mr Shute states) but 30, owing to our discovery of the species *Theobaldia longiareolata* at Portsmouth a few months ago JOHN F MARSHALL

British Mosquito Control Institute, Hayling Island

Infectious Disease in England and Wales

WEEK ENDED DEC 21, 1940

Notifications —The following cases of infectious disease were notified during the week smallpox, 0 scarlet fever 1496 whooping-cough 2395, diphtheria 1378 enteric fever, 16, measles (excluding rubella). 15,221, pneumonia (primary or influenzal), 970, puerperal pyrexia, 108, cerebrospinal fever, 133, poliomyelitis, 13; polio-encephalitis, 3, encephalitis lethargica, 16 (13 at Colchester), dysentery, 152, ophthalmia neonatorum 50 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Dec 27 was 2170, including scarlet fever 304 diphtheria, 325 measles 906, whooping-cough 109, enteritis 30, chicken-pox, 193 erysipelas 51 mumps, 31 poliomyelitis, 1 dysentery 4, cerebrospinal fever, 37 puerperal sepsis 8 enteric fevers, 2 german measles, 4 other diseases, (non infectious) 69 not yet diagnosed, 105

Deaths —In 126 great towns there was no death from smallpox 1 (0) enteric fever, 3 (1) from scarlet fever, 16 (0) from whooping-cough, 16 (1) from measles 39 (2) from diphtheria, 24 (1) from diarrhœa and enteritis under 2 years, and 30 (5) from influenza The figures in parentheses are those for London itself

There was 1 fatal case of enteric fever in Greater London and 1 in Oxford Liverpool reported 5 deaths from diphtheria, Birkenhead 4 and Birmingham 3 There were 5 deaths from whooping cough at Birmingham

The number of stillbirths notified during the week was 204 (corresponding to a rate of 43 per thousand total births) including 14 in London

WEEK ENDED DEC 28

Notifications —The following cases of infectious disease were notified during the week · smallpox 0, scarlet fever 1193 whooping-cough 1846, diphtheria, 1090, enteric fever, 20, measles (excluding rubella), 13 188 pneumonia (primary or influenzal) 857, puerperal pyrexia, 72, cerebrospinal fever 171, poliomyelitis 8, polio-encephalitis, 2, encephalitis lethargica, 2 · dysentery, 112, ophthalmia neonatorum 44 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Jan 3 was 2246, including scarlet fever 316 diphtheria 346 measles 907, whooping-cough 112 enteritis 31 chicken pox 203 erysipelas, 51 mumps 53 poliomyelitis 1, dysentery 10, cerebrospinal fever, 40, puerperal sepsis 8, enteric fevers 6; german measles, 3, other diseases (non infectious) 100 not yet diagnosed, 78

Deaths —In 126 great towns there was no death from smallpox or enteric fever 3 (0) from scarlet fever 16 (1) from whooping-cough 23 (4) from measles 30 (0) from diphtheria, 39 (2) from diarrhœa and enteritis under 2 years, and 40 (1) from influenza The figures in parentheses are those for London itself

Birmingham reported 9 deaths from diarrhœa 4 from influenza and 4 from whooping-cough There were 4 deaths from diphtheria at Liverpool

The number of stillbirths notified during the week was 161 (corresponding to a rate of 53 per thousand total births), including 8 in London

"The superior doctor serves the nation, the middle-grade doctor, the individual, the inferior doctor treats physical ailments"—Proverb from The Chinese Way in Medicine, by EDWARD H HUME (Oxford University Press)

Obituary

HERBERT TILLEY

M D LOND , F R C S

Mr Herbert Tilley, who died at Weybridge on Jan 6, at the age of 71, was one of the later generation of pioneers of rhino-laryngology When he qualified the new specialty was already somewhat grudgingly acknowledged, but Tilley did much to secure a wider recognition for it and to attract the right men to its service

Elliott & Fry

Born at Shepton Mallet, he was educated at Queen's College, Taunton, and at University College, London, where he won many scholarships He qualified in 1890 and took his M D the following year, obtaining his F R C S in 1898 For a time he practised in Hampstead but he was soon appointed to the staff of the Golden Square throat hospital where his junior colleagues have many pleasant memories of his kindness and helpfulness He left to return to his old hospital as the first specialist to be appointed surgeon in charge of the ear, nose and throat department He guided the department with enthusiasm and wisdom, and after its amalgamation with the Royal Ear Hospital he saw it fittingly housed, through the generosity of Mr Geoffrey Duveen, in a new building beside the hospital He was elected a fellow of University College, but outside his school he also held important posts He was laryngologist to the Radium Institute and consulting aural surgeon to the Ministry of Pensions He examined for the University of London, and with Mr Arthur Cheatle he was able to persuade the senate to allow otology, laryngology and rhinology to be taken as part of the M S examination His presidential address to the section of otology of the Royal Society of Medicine in 1919 was an impressive plea for the better teaching of the specialty; he urged medical schools to make an attendance of three months in the ear and throat department compulsory for their students His early experience in general practice had impressed on him the need of attracting to the specialty men with a thorough knowledge of general medicine and surgery, "for," he said, "we can expect little from those who, with a bare qualification to practise, at once focus attention on some special department of the body" He was a regular attendant at the Laryngological Society and later at the corresponding section of the Royal Society of Medicine , when he spoke at these meetings he always had something useful to contribute and was listened to with respect From 1931 to 1932 he served as president of the Medical Society of London, and he was also well known on the continent and in the United States where he was elected a member of the American Laryngological Society

For a long time Tilley felt that his connexion with the board of the Semon lecture trust debarred him from the lectureship But in 1934 he was persuaded to accept and his address on the inflammation of the nasal sinuses was an effective summary of his views on the pathology of sinusitis He contributed many articles to medical textbooks and he almost completely rewrote the fourth edition of De Havilland Hall's Diseases of the Nose and Throat A colleague writes "Tilley was a careful and accurate observer and possessed of sound common sense He had established a solid reputation as a clinician and obtained an extensive practice His charm of manner and attractive personality won for him the affection of his colleagues and of a large circle of patients

LOUIS HENDERSON MACDONALD

M B BIRM , LIEUTENANT, R A M C

Lieutenant L H Macdonald's death was announced in an Army casualty list dated Jan 6 He took his conjoint qualification in 1924 and graduated M B from the university of Birmingham the same year He held house-appointments at the Birmingham General Hospital and was for a time assistant medical officer in the V D department there He afterwards became assistant pathologist and bacteriologist to the Dudley Road Hospital, and a physician there remembers him as a quiet keen worker, always ready to help and a pleasant and agreeable colleague " But he was intensely reserved and had few intimate friends Four years ago he left Birmingham to set up in practice in Portsmouth where he enjoyed his work and was very happy

ROBERT BUCHANAN FORBES McKAIL

M B GLASG , D P M

Dr R B F McKail, who died on Jan 10, after a distressing and protracted illness borne with fortitude, was educated at Allen Glen's School In his student days at Glasgow University he won the Arnott prize, Black medal and Muirhead prize, and after he qualified in 1909 he worked for two years as demonstrator in the anatomy department In 1911, he entered the service of the Lancashire mental hospitals board at the county mental hospital at Prestwich and later served under the same authority at their hospitals at Winwick and Whittingham During the last war, he served as a captain in the R A M C in Gallipoli, Egypt, Sinai and Palestine He was twice mentioned in despatches, but his health suffered and he never fully recovered

On demobilisation in 1920, he was appointed deputy medical superintendent at the Calderstones Certified Institution for Mental Defectives—once again under the Lancashire mental hospitals board, and in 1933 was promoted to be the first medical superintendent of the Brockhall Certified Institution at Langho, near Blackburn In September, 1937, continued ill-health compelled him to retire and he returned to his native city of Glasgow

His wife died three years ago

A colleague writes McKail was a keen follower of sport and athletics and his varied interests made him a most acceptable social companion to all sorts and conditions of men During the last years of his active professional life, his knowledge, energy and mastery of detail were devoted to the preparation of the Brockhall extensions scheme , rapidly failing health prevented him from seeing the fruits of his labours But the institution now almost completed, will stand as a tribute to his wisdom and foresight

THOMAS LAWSON McEWAN

M B ST AND , D P H , F I C

Dr Lawson McEwan, who died on Jan 13, aged 48, was the first bacteriologist of the county of Devon and he did not live to see built the new laboratory which he had planned with so much care

McEwan was educated at the Harris Academy, Dundee, and at the University of St Andrews, where he graduated B Sc in 1914, with honours in chemistry, mathematics and physics He then proceeded to London where he continued to study chemistry and biology at King's College, University College and Birkbeck College Later he became principal assistant to the public analyst for the city of Westminster and for the borough of Fulham At the beginning of the last war he held a commission in the Argyll & Sutherland Highlanders, till at the end of 1916 he was transferred to the Ministry of Munitions as a research chemist The following year he went to the research department at Woolwich Arsenal, and for his work here he was elected F I C

He had always wanted to take up medico-scientific work but the war had interrupted this project Later however, he returned to St Andrews to study medicine He was an outstanding student, and in 1928 he graduated M B with special distinction, gaining the McEwan prize in surgery After serving as house-physician at Dundee Royal Infirmary, he became assistant to Prof W J Tulloch In 1930 McEwan was appointed bacteriologist to the Devon county council He organised this new department with great skill and enthusiasm and gradually built up a first-class laboratory

In 1919 he married Elizabeth Holt Ogilvy, who survives him with two daughters

Notes, Comments and Abstracts

TECHNIQUE OF DIPHTHERIA IMMUNISATION

BY PERCIVAL V PRITCHARD, M D Edin, M R C P E, F R F P S G, D P H
DEPUTY MEDICAL OFFICER OF HEALTH FOR ST PANCRAS

I HAVE lately had many inquiries from doctors about the details of diphtheria immunisation and my object here is to supply the busy practitioner with some easily digested practical notes

Every year many children die from diphtheria or are left seriously crippled by it Babies under one year are seldom affected, but children from one to twelve years are commonly attacked, and the most dangerous period is between one and five After this age many children develop a degree of protection or immunity in a natural way by contact with small doses of the infection

THE SCHICK TEST

The Schick test is performed on children over five as a routine to see if a course of immunisation is necessary *It is also carried out about three months after the final* injection of a prophylactic course at all ages to see whether immunity has been established In any series of cases there is always a small percentage of failures and this test will point these out They should, of course, be given a further course of treatment The test is carried out as follows

Toxin and control can be bought ready for use Into the left forearm 0 2 c cm toxin is injected intradermally Into the right forearm 0 2 c cm of the toxin which has been heated to destroy its specific effect is injected as a control Readings can be made at about 48 hours in an emergency If the result is Schick-positive it can be taken as final A negative result at this stage is unreliable and may change to positive in the next few days A reading seven days after the test is safest

If there is insufficient diphtheria antitoxin present in the blood of the patient the toxin of the Schick test will give a local positive reaction resulting in redness and infiltration at the site of injection This may begin to show itself in 48 hours If present at all it will be there by and on the seventh day It fades in a few days, leaving behind a faint pigmentation and some scales When nothing happens locally the reaction is called negative Considerable experience is required for accurate reading and Schick-testing is usually carried out at special clinics There are two possible readings on each arm, negative (−) and positive (+) Positive results can be (+) or (+ +) depending on the size of the reaction Four interpretations of these combinations are recognised

Left (−), *right* (−) = Schick negative The person is immune The test shows that his blood contains sufficient antitoxin to combat any toxin which would be produced by an attack of diphtheria

Left (+) *or* (+ +), *right* (−) = Schick positive The person is liable to contract diphtheria He should be given a course of immunisation to develop a supply of antitoxin in the blood

Left (+ +), *right* (+) = Schick pseudo positive This is read as a positive reaction, the person being looked upon as susceptible

Left (+), *right* (+) = Schick pseudo negative This is interpreted as a Schick negative result

CHOICE OF A PROPHYLACTIC

I prefer the *toxoid-antitoxin floccules* (T A F) This preparation's great advantage is its freedom from unwanted reactions It is given in three doses of 1 c cm each at fortnightly intervals

Alum-precipitated toxoid (A P T) was originally used for the one-shot method of immunisation I am not going to venture into any of the bitter arguments which have been centred around this material and method I have never favoured it because it has a reputation for causing local nodular reactions Of late its sponsors have advocated turning it into a two-shot method with a first dose of 0 1–0 5 c cm depending on the age, and a second dose of 0 5 c cm four weeks later Some authorities consider these doses to be too high a advise only 0 1 c cm and 0 3 c cm for children and 0 c cm and 0 5 c cm for adults

Toxoid-antitoxin mixture (T A M) is generally c sidered to be less efficient than T A F or A P T in production of immunity

Formol toxoid (F T) has not been used as extensiv in this country as the other preparations It is said give a high percentage of severe reactions particularly older children and adults The latest advice is to g it in three doses of 0 2 c cm , 0 4 c cm and 0 6 c cm w three weeks between the first and second doses and t weeks between the second and third

Whatever material is used it is given intramuscular The makers supply literature with full instructions have given my views but it must be remembered t each of these preparations has its supporters prophylactic course does not guarantee immunity is therefore important that the Schick test should carried out about three months after the last injecti otherwise from time to time immunity will be incorrec presumed with dangerous possibilities

COÖPERATIVE SOCIETIES AND THE SALE OF DRUGS

WHEN the *Pharmacy and Poisons Act 1933* w drafted the Pharmaceutical Society agreed to a provisi that a pharmacist should not conduct a branch sh where drugs were sold under unqualified managemen One would suppose that, sauce for the goose being sau for the gander, it was only right that the same princip should apply to shops belonging to persons who were n pharmacists, but it now appears that such was not t intention of the Government It is now admitte that when the bill was in Parliament the Governme and the all-powerful cooperative societies overlooked t fact that certain clauses would prevent the sale of dru by these societies, the grocery departments of the b departmental stores and like concerns A judgmen given in 1938 by the High Court (Hygienic Stores Ltd Coombes) declared in effect that it was useful for suc traders to sell drugs in grocery departments Since th interpretation the Government have informed th Pharmaceutical Society that it was not intended by the to prevent, by the 1933 act, the sale of drugs in th grocery sections of such concerns and they have no intimated that the act ought to be amended by provision to the effect that where drugs (other tha Part 1 poisons) are sold " on registered premises inci dental to and as a subsidiary part of a business of different class carried on by the authorised seller o poisons, nothing in sections 8, 9, and 10 of the act shal require such sale of drugs to be under the persona control of a registered pharmacist subject to the observ ance of the following conditions (*a*) that the drugs ar sold in closed containers as closed by the manufacture or other person from whom they were obtained, (b that no drugs are compounded or dispensed on th premises, and (*c*) that no title, emblem or description the use of which is restricted by section 3, is used i connexion with the business carried on in these premises " The whole question was reviewed at th society's January council meeting and it was decided to ask the Home Office to receive a deputation from th council to discuss the matter further on the basis of the proposed amendment From the fact that the Govern ment are desirous of a settlement in war-time it may b assumed that they regard the question as an urgent one

AN OUTBREAK OF "PEMPHIGUS NEONATORUM" IN A MATERNITY HOME

By S. D. Elliott, M.B. Lond., D.P.H.
BACTERIOLOGIST AT THE EMERGENCY PUBLIC HEALTH LABORATORY, HAILEYBURY COLLEGE, HERTS

E. Harper Gillespie, M.B. Edin.
BACTERIOLOGIST IN THE DEPARTMENT OF BACTERIOLOGY AND PREVENTIVE MEDICINE, UNIVERSITY OF MANCHESTER, AND

Eardley Holland, M.D. Lond., F.R.C.P., F.R.C.S., F.R.C.O.G.
OBSTETRIC AND GYNÆCOLOGICAL SURGEON TO THE LONDON HOSPITAL, COUNTY OBSTETRIC CONSULTANT FOR HERTS

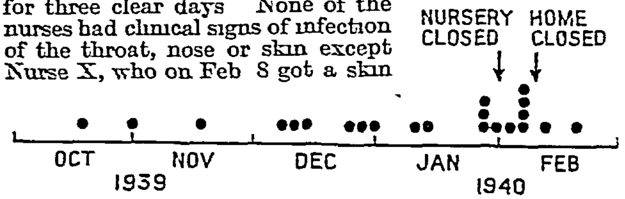
This outbreak of mild staphylococcal skin infection, which affected 22 infants, 2 mothers and a nurse, occurred between October, 1939, and February, 1940, at a maternity home. We use the word "pemphigus" because it is in common usage to describe this type of skin infection in the newly born. The term "bullous impetigo," often used alternatively, does not properly describe the condition, because in this epidemic, which appeared to conform fairly closely with the mild type of pemphigus described in the Ministry of Health's memorandum (1925), bullæ did not appear. We agree with Carter and Osborn (1938), who described an epidemic in many respects similar to ours, when they propose the term "contagious subepithelial dermatitis."

HISTORY OF THE OUTBREAK

The home, formerly a private residence, has beds for 38 women. It is fully equipped, adequately staffed with midwives and nurses, has an isolation-room, and the beds are properly spaced. The nursery, with accommodation for 20 infants, is 24 by 18 ft. and 11 ft. high, with a window 8 ft. square on one side facing the door. A day and a night nurse were on full-time and two other day nurses on part-time duty in the nursery. The night nurse (Nurse X) was on duty in the nursery from the date it opened (September, 1939) until Feb. 8, 1940, when she was suspended from duty because of an infective skin lesion. On Jan. 30 the nursery began to be used for infected infants only, the healthy infants, including the 4 born after that date, being isolated in another room. Nurse X was thus the only nurse who was continuously (except for days off duty after the occurrence of each case of infection) in charge of all the infants born in the home except the last 4, coming into close contact with them during bathing, changing napkins, feeding and so on. Of the last 4 infants born, only 1 became infected, and it is of interest that this infant was looked after by the nurse who shared a bedroom with Nurse X. These points are emphasised in view of the bacteriological findings and the sites of the primary skin lesions.

The first baby to show signs of infection was born on Oct. 16, 1939. The mother had 3 other children who, just before the confinement, had been admitted to a local hospital with profuse impetigo. It was found out later that the father had been in the habit of visiting them in hospital and then going on immediately to the maternity home to see his wife and baby. This infant when six days old developed an infective eruption from which a pure culture of *Staphylococcus aureus* was obtained; these organisms were not examined in further detail. Both the mother and infant were removed to a hospital whence four days later they were discharged, the rash having dried up and almost gone. The dates of the first appearance of the infection in the 22 cases is shown in the figure and table I. The last of the babies to become infected was born on Feb. 11. The mother was admitted although the home had been closed to new admissions since Feb. 2, because on her arrival the baby was on the point of being born. On Feb. 14 the home was temporarily closed for fumigation. No fresh cases have occurred since it was reopened on March 11.

The infected babies were removed, directly they showed signs of the disease, to a separate ward in which they were nursed by a separate nursing staff. After Jan. 30, as already stated, this arrangement was reversed, the nursery being reserved for infected babies only. Isolation was not always complete, however, since all those affected were breast-fed and the mothers of infected and uninfected babies sometimes occupied the same ward. Moreover, the separate nursing staff lived in the same quarters as the ordinary nursing staff and fed at the same table. Whenever a case occurred the day and night nurses who had been in contact were at once taken off duty, followed the usual routine of disinfection of person and clothing, and were sent away from the home for three clear days. None of the nurses had clinical signs of infection of the throat, nose or skin except Nurse X, who on Feb. 8 got a skin lesion on the back of her hand and was forthwith suspended from all duty. A similar lesion had appeared a week before on her elbow; this, unfortunately, she failed to report, and it remained unnoticed. From the hand lesion staphylococci were isolated which corresponded serologically with those recovered from the eruptions in the infants.



Dates of onset in the 22 cases

In February two mothers whose babies were affected developed a similar eruption on the skin of the breast; both infants were breast-fed. In both cases the infection appeared in the month *after* the baby had contracted the disease.

Face-masks and gowns were always worn by nurses on duty in the nursery but rubber gloves were not used until mid-way through the outbreak, after which they were always worn when handling the infants. This measure did not have any observable effect on the spread of infection.

TABLE I—INCIDENCE OF PEMPHIGUS AT THE HOME

Month	Babies developing pemphigus	Babies born at the home
September	0	34
October	2	32
November	1	17
December	6	19
January	6	11
February	7	4

SKIN LESIONS

Some exposed area of skin—the face, scalp, neck, hand, buttocks and thighs (exposed during changing napkins)—was almost always the first to be affected. After the occurrence of the first case a careful look out was kept for the first sign of a rash, so that the primary sites were noted and recorded. In 7 it was on the face, in 1 the scalp, in 2 the neck, in 7 the hand, and in 1 each the buttock, thigh, elbow and shoulder. In the face it was often on the margin of the eyelid or the outer canthus; on the hand it was usually at the base of a finger-nail. A small clear-cut red area, a small red spot, or a small crop of confluent spots first appeared. The time of appearance varied from the second (1 case) to the twelfth day (2 cases) after birth, more than half being from the fourth to the sixth day inclusive. In a few hours the cuticle over the affected area became yellowish, wrinkled and loose. The quantity of fluid secreted amounted to no more than a film sufficient to separate and slightly raise the cuticle, only once during the whole outbreak was a small blister, of very short duration, seen. The cuticle quickly broke, exposing the superficial layers of the cutis. The exposed areas were at first bright red and moist, but quickly dried and faded and healed rapidly. The primary lesions were almost invariably followed by similar but more extensive lesions, and in this way large areas of skin, especially over the trunks and buttocks, were denuded of epidermis None of the infants appeared ill or had pyrexia or other signs of infection, all continued to thrive and gain weight, and none (except 2 premature infants) remained in the home more than fourteen days The breast eruptions of the 2 mothers were confined to the superficial layers of the skin and did not lead to abscess formation Indeed, no breast abscess or other type of septic infection occurred in the home throughout the epidemic, and the incidence of puerperal pyrexia did not rise In the infected nurse the skin lesion on the hand appeared to be rather more deeply seated but when seen there was no pus

BACTERIOLOGICAL INVESTIGATION

Exact bacteriological details are available only for the cases occurring during February, at the end of the outbreak Swabs from the skin lesions were taken for examination The cases examined in this way included the last 8 infected infants, the 2 mothers with skin lesions on the breast and the nurse (Nurse X) with a lesion on the back of the hand

The swabs were inoculated on nutrient agar and 5% horse-blood agar plates which were incubated at 37° C for eighteen hours and thereafter left on the bench for several days to facilitate the production of pigment in colonies of staphylococcus Representative staphylococcal colonies were selected and tested for fermentation of mannitol and coagulase production All "coagulase positive" strains were identified serologically by one of us (E H G) by the slide agglutination method (Cowan 1939), dividing the strains into the three main types I, II and III, and into additional subtypes according to the reactions with absorbed sera (Gillespie and others 1939) The sera were supplied by Dr S T Cowan of the department of bacteriology and preventive medicine, Manchester University

From all cases except one almost pure cultures of *Staphylococcus pyogenes* were obtained * These produced golden pigment on agar, fermented mannitol slowly (3–5 days) and coagulated human plasma They also produced a narrow zone of hæmolysis on horse-blood agar but the strains were not tested for soluble hæmolysin Serologically they all belonged to type IIIc (Cowan) (table II) In the one exception which gave a few colonies of *Staph saprophyticus albus* the lesion had been painted with an antiseptic immediately before the swab was taken

TABLE II—STAPHYLOCOCCI ISOLATED FROM SKIN LESION IN 11 CASES

Source of staphylococci	Cases examined	Cases yielding *Staph pyogenes*	Serological type (Cowan)
Infants' skin	8	7	IIIc
Mothers' breast	2	2	IIIc
Nurse's hand	1	1	IIIc

NASAL CARRIERS

McFarlan (1938) and Gillespie and others (1939) have shown that *Staph pyogenes* is present in the nose of over 40% of the population It was possible that amongst the nurses there was a carrier of the causal strain of staphylococci Throat and nose swabs were therefore taken from the entire nursing staff, but in no instance was a profuse culture of staphylococci obtained from the throat * *Staph pyogenes* was obtained from 9 nurses, the incidence of serological types being type I, 4 times, *type IIIc, once, type IIId, 3 times*, and an unknown type once One colony only was identified from each culture

The nurse found to be harbouring *Staph pyogenes* type IIIc in the nose was Nurse X She had, at the same time, a staphylococcal lesion on the hand and a week before had had a similar lesion on the elbow Type IIIc staphylococci were recovered from her hand but the elbow was not investigated

AIR INFECTION

Blood-agar plates were exposed to the air in the home during the outbreak on one occasion from 6 A M until 12 noon, two plates being exposed in each room tested They were subsequently incubated overnight at 37° C after which 2 representative staphylococcal colonie resembling those previously isolated from the skin lesion cultures were selected from each plate and teste for coagulase production, coagulase-positive strain were then identified serologically

Staph pyogenes type IIIc was recovered from th plates exposed to the air in the nurses' dining-room, nursery containing 2 infants with skin lesions and a war accommodating 2 mothers both with breast eruption and 1 with the same staphylococcus in the nose W were unable to recover this type of staphylococcus from plates exposed in 2 unoccupied wards or in a ward containing an uninfected mother Swabs from doo handles, bed linen and furniture in wards containin infected patients also failed to reveal the presence of thes staphylococci, only 1 colony was tested from eac culture taken from these situations

DISCUSSION

Although a full bacteriological investigation was onl made in the later stages, it is likely that the whole outbreak was due to *Staph pyogenes* type IIIc (Cowan Skin carriers of *Staph pyogenes* are fairly commo comprising 19 5% of a group of 159 students examined b Gillespie and others (1939), of these carriers about on in ten were carriers of type IIIc The isolation in profus culture of this serological type from 10 out of 11 cases i thus very unlikely to have been due to chance It wi be recalled that in the single exception the lesions ha been painted with an antiseptic immediately before th swab was taken

It is impossible to determine conclusively the source o the means of spread of the infection There were a least two possible sources of primary infection Th first was the 3 cases of impetigo occurring outside th hospital, the infection being introduced by the father o the mother This point was not investigated Th second possible source was the nurse from whose nos and hand lesion *Staph pyogenes* type IIIc was isolated Gillespie and others (1939) have shown that staphylococcal nasal carriers tend to persist and that skin carriage i closely related with nasal carriage Provided the nurs was a chronic carrier before the outbreak, her close contact with the infants would have given ample opportunity for infecting them Alternatively she may hersel have been infected by an infant during the early stage of the outbreak There are three possible means o spread—by contact with the carrier nurse, through contaminated garments, gowns, gloves, hands and so on, an by the air The last two involve the possibility of case-to-case transfer The presence of the causative organism in the air of the wards in which the cases occurred and i the nurses' dining-room indicates the prevalence of tha particular strain of staphylococcus in these situation during the outbreak and suggests that aerial transmission may have been a factor in the spread of the disease On the clinical side the outstanding feature of the outbreak was the mildness, even triviality of most of th cases, in 10 there was only one spot (in half of them o a finger) which was well in three days It is easy t overlook such a trivial case and to fail to realise that suspicious spot may be the prelude to an epidemic an the danger signal that a source of infection exists

Although inconclusive, the available evidence suggest that contact infection by Nurse X was an importan factor in maintaining this outbreak and may even hav been the original source of infection

SUMMARY

An outbreak of skin infection resembling pemphigu neonatorum occurred in a maternity home, 22 infants, mothers and 1 nurse were affected

Profuse, almost pure cultures of *Staph pyogenes* wer obtained from the lesions in 10 out of 11 cases examine bacteriologically and all were found to be type III (Cowan)

A nurse who had two skin lesions was a nasal carrier staphylococci of the same type Staphylococci of th type were also recovered from plates exposed to the a during the outbreak in two wards in which were infecte patients and in the nurses' dining-room These organism

---

* Hæmolytic streptococci were never isolated from the throats or noses of the nursing staff or from the skin lesions of the infants, mothers or nurse X

were not isolated from the air of two unoccupied wards or a ward containing an uninfected patient

The evidence suggests that the nurse may have been the source and also the means of spread of the infection

Our thanks are due to Dr S T Cowan for the use of his staphylococcal type sera for this investigation

OPIUM AS A PREANÆSTHETIC SEDATIVE IN CHILDREN

By A H L Baker, B.A Oxfd, L M S S.A , D.A

AND

E M Chivers, M B Cape Town, D.A

ANÆSTHETISTS TO WEST MIDDLESEX COUNTY HOSPITAL, ISLEWORTH

Preanæsthetic sedation in children has always presented a problem to the anæsthetist Nobody likes seeing a terrified child arriving crying at the operating-theatre, as so often happens when no premedication, or only an injection of atropine, has been given Conversely the administration of an anæsthetic to a child deeply under the influence of some hypnotic is not without danger

The barbiturates, especially Nembutal, have been used widely as a preanæsthetic sedative for children but in our experience the action of this group of drugs is unreliable After an adequate dose a child may be either asleep or restless before operation and postoperatively either recover quietly or be difficult to control for a time, one noisy patient is enough to upset an entire children's ward Another difficulty is the impossibility of persuading some children to swallow capsules even when disguised in jam or sweets Rectal paraldehyde and Avertin cannot always be given in a busy children's ward and are certainly not the preanæsthetic of choice in every case

Opium derivatives are seldom administered to children, possibly because of a traditional prejudice against them, but investigation has shown (B C Leech 1935, C H Robson 1936) that these drugs are extremely well tolerated The requisite dose consistent with safety depends on the patient's basal metabolic rate, and the relatively high rate found between the ages of 1 and 20 years when compared with that of adult life has been amply shown in the work of Du Bois and Benedict (1924) The rates of infants aged 1–3 months and 1 year are respectively the same as those of adults aged 80 and 20 years Between 1 and 20 the rate rises sharply to a maximum at 6 years, declines up to 12 years, and reaches almost the same high level again at puberty before the gradual decline towards old age We found that whereas an adult weighing 133 lb (average) took morphia gr ⅙ or Omnopon gr ⅓ satisfactorily a child of 1 year (average weight 20 lb) tolerated morphia gr 1/40 or omnopon gr 1/21 equally well The table given here is based on that in Leech's article (1935), the dose of morphia in each case being the nearest convenient fraction of gr ¼ or gr ⅙ to the appropriate calculated dose The omnopon dosage was based on the fact that gr ⅓ of this drug contains morphia gr ⅙, plus the other active principles of opium, and was therefore usually just under double that of morphia

To inhibit mucous secretions, hyoscine was given in properly balanced doses with the opium derivatives The drug is a metabolic stimulant, but this action is counterbalanced by its power to reduce emotional excitement, thus the sedative action of the opium is left unimpaired and can be exercised to the full Furthermore having no vago-inhibitory action, hyoscine does not produce tachycardia, as atropine does occasionally when used alone Many anæsthetists now avoid atropine as being too stimulating to be a good preanæsthetic

RESULTS

The table shown here was used with satisfactory results in a series of 600 children aged from 1 month to 16 years There were a few failures at the beginning from over-caution and under-dosage Most of the children arrived in the theatre in a drowsy and unapprehensive state, taking a detached view of the proceedings, a small proportion was asleep and not easily disturbed Inductions were smooth, amount of anæsthetic used reduced, and postoperative consciousness quickly regained with a minimum of restlessness, this last point is valuable after tonsillectomy In some minor procedures, such as the changing of dressing and plaster, these drugs were sufficient unsupplemented by anæsthesia Postoperatively, the retrograde amnesic effect of hyoscine has been present in most of our cases a fact testified to by the ward nurses who get this information easily in the course of daily routine The anæsthetist is usually confronted with a barrier of shyness when he makes a personal quest for information

The table doses were slightly exceeded without incurring dangerous symptoms in children who were obviously excitable and had an increased B M R, and in those who were overweight for their age-group (excluding the over-adipose who often tend to be under-developed in all other respects and may require reduced dosage) No instance of abnormal B M R due to endocrine disturbance was encountered in this series

DOSAGE OF MORPHIA OR OMNOPON WITH HYOSCINE ACCORDING TO AGE

Age (years)	Average weight	Either morphia (gr)	or omnopon (gr)	With hyoscine (gr)
Up to 6/12	Variable	Not tried	1/30 (not tried under 3 months)	1/1200–1/900
6/12–1	18½ lb	Not tried	1/30–1/24	1/900
1–2	22 lb	1/40	1/24–1/21	1/600
2–4	2 st 2¾ lb	1/32	1/18–1/15	1/600
4–8	3 st	1/20	1/12–1/9	1/450
8–12	4 st 5½ lb	1/16	1/9	1/450
12–16	6 st 6 lb	1/12	1/6	1/300

A few emergency cases with pain and fever benefited less than other children from the doses given presumably because their B M R was raised but for reasons of caution no attempt has so far been made to increase the dosage Patients of advanced development in the 12–16 year group often took satisfactorily the full adult dose of omnopon gr ⅓ or morphia gr ⅙ with hyoscine gr 1/150

It is, of course, important that the fractional doses of drugs should be accurately worked out To avoid confusion and mistakes we employ the method practised at this hospital for many years, of double check for every injection given

SUMMARY

Opium derivatives are well tolerated by children.

Dosage depends on the basal metabolic rate, which increases to a maximum at the age of 6 declines up to 12, rises again during puberty and then declines throughout life

The appropriate dosage of morphia, omnopon and hyoscine were calculated for children of all ages under 16

Morphia and hyoscine or omnopon and hyoscine administered in the calculated doses were satisfactory as preanæsthetic sedatives in 600 children between the ages of 1 month and 16 years

Our thanks are due to Dr I W Magill for suggesting this work and for his help and criticism, and to Dr J B Cook, medical superintendent of the West Middlesex County Hospital, for permission to publish this paper We also wish to thank the nursing staff for their coöperation

INJURY TO THE CENTRAL NERVOUS SYSTEM BY BLAST

OBSERVATIONS ON A PHEASANT

BY
OSCAR W STEWART, M D
CAPTAIN R C A M C
COLIN K RUSSEL, M D
LIEUT COLONEL R C A M C , AND
WILLIAM V CONE, M D
LIEUT COLONEL R C A M C
(*From No 1 Canadian Neurological Hospital*)

BLAST effects from high explosives, which produced no marks of external violence but nevertheless caused instantaneous death, were described in the last war Examples are also cited in which death was not immediate, and in some of these evidence of injury to the central nervous system was apparent during the hours or days preceding death That definite pathological changes in the central nervous system can be caused by blast was shown by Mott (1916 and 1917) when he recorded the macroscopic and microscopic abnormalities in brains and spinal cords of soldier casualties His findings were widely and uncritically accepted as the explanation for the variable and bizarre symptom-complex popularly referred to as " shell shock "

Again in this war there have been reports of the damaging effects of blast on vertebrates The human material studied has been largely from fatal cases Damage to the lungs characterised by alveolar ruptures and hæmorrhages has been the consistent and dominant feature Hadfield, Ross, Swain and Drury-White (1940) cited 10 cases of sudden death in persons subject to the blast effect of high-explosive bombs In none of these was there any evidence of external trauma , there were gross hæmorrhagic lesions in both lungs in all, and blood-stained secretions in the upper air-passages in some Microscopic examination of other tissues was not mentioned in this preliminary report, but its authors felt that the lung damage, even though severe in some cases, was not sufficient to cause sudden death They looked on this finding rather as an unmistakable indication that the patient had suffered considerable blast effect " It seems more likely," they conclude, " that blast produces death by interfering with some vital tissue or centre in which, from the extreme rapidity of action, structural changes are unlikely to be found " Falla (1940) reported a case with capillary hæmorrhages in both lungs due to blast and Zuckerman (1940) has published his experimental findings in animals subjected to blast He found extensive hæmorrhages in the lungs in all fatal cases and less severe lesions in animals surviving the immediate blast effect The severity of the pulmonary lesions was roughly dependent on the nearness of the animal to the explosive discharge No detailed mention is made in this report of examination of other tissues Zuckerman concludes from these experiments that it is the pressure component of the blast which bruises the lungs by its impact on the body wall

We have seen a small series of patients who have been exposed to blast and have exhibited a variety of neurological abnormalities Some, without showing focal signs, have simply been apathetic and indifferent, others have been depressed, and one, seen some days after the injury, had xanthochromic spinal fluid although there was no mark of external violence to the head or spine In another there were signs of spinal-cord damage limited to the anterior horn cells We have theorised that the symptoms might be due to the hydraulic-like pressure on the central nervous system in its firm encasement, resulting from the sudden compression of the thoracic cage with its consequent violent back-pressure on the venous side

The neurosurgeon is all too familiar with the sudden and alarming herniation of the brain that can take place through a widely opened dura when a patient under local anæsthesia coughs unexpectedly, and he is also familiar with the changes produced in the circulation in the meningeal racchidian veins of the vertebral extradural space and in the circulation of the spinal cord itself in such a situation The sudden compression of the thorax forces blood out through the various venous channels, valveless or incompetently valved, that drain the cranial cavity and the spinal canal This results in a sudden and striking increase in intracranial and intraspinal pressure This pressure in the closed intracranial and intraspinal cavities would presumably be incomparably greater when caused by a blast wave than when produced by coughing, in that the compression of the body surface generally would prevent the escape of blood into the extremities and abdomen, and intracerebral hæmorrhages may certainly result from paroxysmal coughing in children with whooping cough

THE BLASTED PHEASANT

We have collected a bit of evidence from the study of a pheasant which was suffering from blast effect, which lends some support to the speculations advanced with regard to the mechanism of injury The bird was found ninety feet from the edge of a bomb crater twelve hours after two large bombs had been dropped in a wooded patch the previous night There was no way of determining how near to the explosion the bird had been It was standing on both legs with the eyes closed most of the time (fig 1) It did not move when approached and there was no reaction of fear or resistance when it was picked up When placed on its feet and pushed along it would take a few unsteady steps with legs tending to cross and then came to a standstill It could be placed in any position and would remain in that position until moved Even when placed on its back and in other unusual positions it exhibited a waxy flexibility that closely resembled the catatonic patient (fig 2) Our zest for a thorough anatomical scrutiny of the bird was surpassed only by the gastronomical designs of the gamekeeper who happened upon it at about the same time A compromise was effected and an hour after it was found (13 hours after the bombing) the bird was killed by cutting the large vessels in the neck and allowing it to bleed freely The brain was carefully removed with the dura intact The feathers were plucked and a thorough search revealed no external evidence of trauma All organs were removed and together with the brain placed in 10% formalin

Gross findings —Discoloration of the undersurface of the forebrain beneath the dura was the only gross finding in the uncut brain Both lungs showed much hæmorrhagic congestion—the left one appearing solid and beefy red, resembling the stage of red hepatisation in lobar pneumonia There were no hæmorrhages along the ribs nor were there any fractured ribs No gross lesions were observed in the other organs On sectioning the brain there were gross hæmorrhages *in the forebrain* extending backwards as far as the ventricle (fig 3) No hæmorrhage could be seen macroscopically in the mid brain or cerebellum Cut sections of both lungs showed extensive hæmorrhagic consolidation (fig 4) The heart, liver and spleen showed nothing abnormal macroscopically The sections were embedded in celloidin and cut Hæmatoxylin - Van Gieson stains were done on all tissues and some sections of the brain were also stained with toluidin blue

Microscopic findings —*Brain* Throughout the cerebrum the capillaries

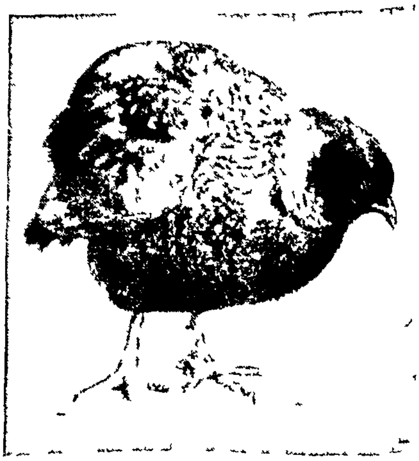

FIG 1—Position of pheasant when found Note dejected appearance and closed eyes

FIG 2—One of several attitudes maintained indefinitely after posturing

re congested and in the forebrain on both sides ere were numerous hæmorrhages of varying sizes ese seemed to be chiefly associated with the small ins and to a lesser extent the capillaries Many these formed a collar about the vessels with the ood-cells extending outwards and separating the uroglial framework about them No consistent ange could be seen in the nerve-cells with the stains nployed We were struck by the presence of numerous emorrhages surrounding the ventricle in the hypo- alamic region In two areas, clusters of blood-cells were nging to the inner surface of the ventricle In the rebellum four small hæmorrhages were found in one ction *Lungs* Massive hæmorrhages were found in oth lungs In many areas the small bronchioles and ronchi were occluded with blood and mucus Many lveoli were ruptured in addition to containing red blood- ells *Heart* Deep in the muscular layer of one entricle there were numerous small hæmorrhages hese were associated with very small vessels Other- ise the vessels and musculature appeared normal

FIG 3—Section through forebrain showing hæmorrhagic area

DISCUSSION

This report is presented to call attention again to the fact that lesions of the central nervous system can be produced by blast Though pulmonary damage is apparently a constant finding and at times is very extensive it seems unlikely that it is responsible for either sudden death or later fatalities except in a contributory way It seems likely that under certain conditions the hydraulic-like force acting on the central nervous system may, when of the right degree cause cessation of nerve-cell activity without producing macroscopic or microscopic evidence of injury—in other words, it may produce the clinical picture of concussion

In the two cases reported by Mott (1917) both of the soldiers were exposed to the blast of high explosive shells Neither showed external signs of injury The first man was admitted to hospital in a state of acute mania and died suddenly 24 hours later The only gross pathological finding outside the brain was a large hæmorrhagic area in the lower lobe of the left lung Both lungs were œdematous Summarising the histological changes in the brain Mott reported " vessels of the pia-arachnoid membranes of the brain are congested and there are scattered sub pial hæmorrhages of microscopic size almost everywhere In the white matter of the corpus callosum, the internal capsule, the pons, and medulla there are seen congested veins and hæmorrhages into the sheaths of these vessels with occasionally extravasation of blood corpuscles into the adjacent tissue " The second patient became comatose immediately after an explosion and died the same day without regaining consciousness In this case only the examination of the brain is reported Here again the striking finding was the presence of hæmorrhages of varying degree into the substance of the brain

A third case is described in the same article by Mott A soldier was brought in from no man's land with a superficial graze over the spine of the left scapula and a small "in-and-out" wound of the right gluteal region He was mentally clear but drowsy with "halting speech" There was complete paralysis of the legs and abdominal muscles and the left side of the face Power in both arms was diminished The level of complete anæsthesia was at the umbilicus Rectal and vesicle sphincter control were lost This patient gradually became comatose and died seven days later A complete post mortem examination was made and nothing to account for death was found Sections of the spinal cord from D 8 to L 2 inclusive were examined microscopically and the appearances, though varying in intensity, were similar in all of them On the surface there was evidence of subarachnoid bleeding The surface veins were congested though the arteries and capillaries were relatively empty "In places," Mott wrote, "the veins could be seen ruptured and in some sections intraradicular hæmorrhage was observed In the substance of the spinal cord itself were numerous minute hæmorrhages, varying in size from a pin head, and visible to the naked eye, to a pin-point, invisible except by the aid of the microscope The hæmorrhages are seen especially in situations where the surrounding tissue offers least support, consequently they are found in the grey matter of the anterior horns, but especially at the base of the posterior horn near the central canal "

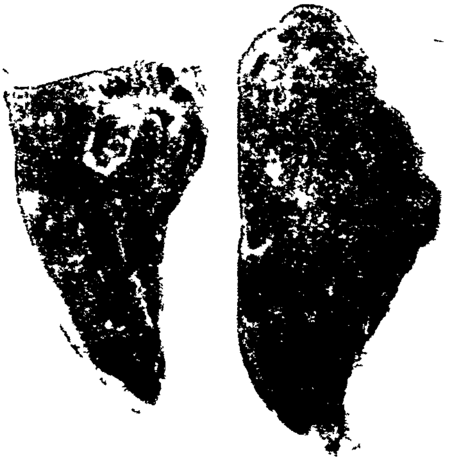

FIG 4—Sections of right and left lung showing hæmorrhagic consolidation.

Mairet and Durante (1917, cited by Mott) subjected rabbits to blast by means of melinite explosions Histological examination showed diffuse hæmorrhages in the lungs, spinal cord and brain hæmorrhage in the kidney was found in one animal

Mott thought that the aerial compression generated by high explosives might be transmitted to the fluid about the base of the brain, causing shock to the vital centres and death He considered too that the forces of compression and decompression might both act on the central nervous system producing arterio-capillary anæmia, venous congestion and rupture of small vessels He did not explain, however, how the forces were brought to act on the circulation

We have purposely omitted any consideration of the decompression effect or "suction wave" in our discussion, although it is, together with the compression effect, embraced in the term "blast" Lieut -Colonel Arthur James [1] after experimenting with low-pressure effects, feels that the negative pressure wave following the positive one may, in the suddenness of the change, be an important factor in cerebral injury But there is sound experimental evidence that this suction effect is of little significance in the production of the pulmonary lesions (Zuckerman 1940)

From the experimental reports and case-records to date it seems clear that the effect of the blast wave on man and animals sufficiently near and directly in the path of this violent compression force may be so damaging as to cause instant death Lesser degrees of injury may also occur, as exemplified by the cases which live for hours or days after exposure and show definite pathological lesions in the post-mortem examination, by cases which have coexisting wounds from the shell or bomb fragments which overshadow the signs of the lesions produced by the blast alone, and finally, by the milder cases which, recovering without showing definite signs, make it impossible to prove the existence of minor lesions or to establish the fact that concussion of the central nervous system was produced

---

[1] Personal communication

We are diffident to suggest, from our circumstantial evidence, that blast affecting the central nervous system can produce a symptomatology ranging from slight mental disturbance to signs of damage to the anterior horn cells Yet we have encountered such varied signs in our small series of patients exposed to blast, and on theoretical grounds can visualise pathological and physiological disturbances as varied as the symptomatology It is important that all this should not be construed, as it was in the last war, as justifying the term "shell-shock" with all its connotations The changes we are discussing should be transitory in the less severe disturbances, but if permanent they should be measurable by abnormal neurological signs or electro-encephalographic studies (Jasper, Kershman and Elvidge 1940) The problem of differential diagnosis between organic disturbances and purely psychogenic disorders remains

SUMMARY

A pheasant found after an air-raid suffering from the blast effect of a high-explosive bomb was in a dazed condition resembling catatonia There were no external injuries but hæmorrhagic lesions were present in the lungs and heart muscle, and in the brain there was capillary congestion throughout the cerebrum with gross hæmorrhages in the forebrain

We suggest that the mechanism responsible for the cerebral lesions was the hydraulic-like pressure on the central nervous system, in its firm encasement, resulting from sudden compression of the thoracic cage with consequent violent back-pressure on the venous side

PARATYPHOID ABSCESS

RECOVERY OF ORGANISM FROM BONE-MARROW

By A Macdonald, M B Aberd
GARDEN RESEARCH FELLOW IN THE UNIVERSITY OF ABERDEEN

SIMPLE abscess caused either by *Bacterium typhosum* or *Bact paratyphosum* B is listed by Browning along with the less common complications such as perichondritis, periostitis and middle-ear involvement It is not often mentioned as a possible source of an outbreak of enteric infection, and this is apt to be forgotten

In the first case a breast abscess caused by *Bact paratyphosum* B developed two months after the patient's discharge from hospital and the infecting organism was found in the sternal bone-marrow at a time when it could not be recovered from any other source The second patient's symptoms were more severe and therefore more likely to be fully investigated, but both histories underline the need for careful examination of abscesses in patients with a recent enteric infection

CASE-RECORDS

CASE 1 —A woman of 38 became ill on July 20, 1940, and was diagnosed as suffering from paratyphoid fever on Aug 3 when she was admitted to the City Hospital, Aberdeen On this date her stools gave an abundant growth of *Bact paratyphosum* B and her serological reactions were typical of that infection, but the organism was not found either in her urine or on blood culture The patient was never acutely ill and by Aug 15 her temperature was normal and her fæces free from the infecting organism Repeated culture both of the urine and fæces between this date and her discharge on Sept 19 was negative

During the first examination of the patient in hospital a small painless lump with indefinite edges was found in the right upper quadrant of the left breast The patient thought it had been present before the onset of her illness, and it was considered to be an area of chronic mastitis During convalescence, on Aug 20, she complained of a dull ache in this breast, which however was not inflamed, and the pain disappeared in a week or two She was advised to have the breast examined at the outpatient department of the Aberdeen Royal Infirmary, and on Sept 20 she reported that the lump no longer troubled her and was getting smaller, so she was told to return for periodic examination On Nov 21 the breast became inflamed and a week later a superficial abscess developed over the site of the original lump The abscess was incised and yielded a small quantity of thin pus which on film was predominantly polymorphonuclear and contained gram negative bacilli On plating out a pure culture of *Bact paratyphosum* B was grown The abscess began to heal rapidly after incision, though the original tumour remained, and two days later and on subsequent examinations only *Staphylococcus albus* was found in the discharge Repeated clinical and two radiographic examinations gave no evidence of involvement of bone or periosteum On Dec 3, after three negative examinations of swabs from the breast wound, sternal puncture was performed By inoculating 0 5 c cm of marrow fluid into 20 c cm of MacConkey broth and meat infusion broth *Bact paratyphosum* B was obtained

CASE 2 —A woman of 43 was admitted to the City Hospital, Aberdeen, on Sept 12, 1940, suffering from paratyphoid fever Her illness was of moderate severity but she persisted in excreting *Bact paratyphosum* B in her fæces for some weeks after admission to hospital She was discharged on Dec 12, when repeated examination of her fæces, urine and bile had apparently shown that she no longer harboured the infecting organism During convalescence sternal puncture was performed but *Bact paratyphosum* B was not obtained A few days after leaving hospital the patient complained of lower abdominal pain and difficulty in micturition and on Dec 30, when she was admitted to Aberdeen Royal Infirmary, the pain had become severe and she was found to have an abscess arising from the pelvis and reaching to the level of the umbilicus The abscess was opened through the pouch of Douglas and a large quantity of pus removed In films the cells were almost all polymorphonuclear and no organisms were seen, but *Bact paratyphosum* B was found on culture On Jan 7 culture of the blood and fæces was negative but *Bact paratyphosum* B was grown from the sternal marrow fluid

COMMENT

Abscesses caused by the organisms of typhoid and paratyphoid fevers are uncommon but important because unlike many other complications they may produce little systemic effect and because they exactly simulate an ordinary pyogenic abscess The first patient was nursed at home after the breast was opened, and had the surgeon not insisted on bacteriological examination the possibilities of spreading her infection would have been great As to the time and manner of the invasion of the breast tissue and as to whether the presence of *Bact paratyphosum* B in the bone-marrow played any part in it there can be only speculation, but the finding of the organism in the sternal marrow after it had disappeared from all other sources is of interest from the carrier point of view In the second patient sternal-marrow culture was negative when the other investigations were also negative, and it may be significant that both positive marrow cultures were found fairly soon after surgical interference These are unfortunately isolated and may be fortuitous findings, but there is experimental evidence that the enteric organisms may persist in the marrow for long periods Browning (1933) quotes the recovery of *Bact typhosum* from the marrow of a rabbit 162 days after intravenous inoculation when the liver, gall-bladder and bile were free, and Coplans (1936) in a series of 104 rabbits recovered the same organism in 90% of instances up to the 27th week Ling and his colleagues

(1940) lately described the value of sternal-marrow culture as compared with blood-culture in typhoid fever , in one patient they found that the bone-marrow still harboured the organism on the 67th day of illness, and in another patient that medulloculture was positive two weeks after convalescence was well established (see *Lancet*, 1940, 2, 169) It has also been said that the bone-marrow forms a depot for the organism in the true relapse which sometimes follows enteric infections Browning's study of the treatment of carriers shows that, though surgical treatment is satisfactory, in about a quarter of the cases cure may not result If the gall-bladder is to be considered a test-tube for the growth of the enteric organisms in the carrier may it not be that, in some instances at least, the reticulo-endothelial cells of the bone-marrow continue to act as the platinum loop ? Further investigation of the bone-marrow in the unexplained carrier may be worth while

I wish to thank Prof John Cruickshank for help , and Dr John Smith, regional bacteriologist, and Mr G Gordon Bruce, surgeon to Aberdeen Royal Infirmary, for access to their records

A TELLURITE BLOOD-AGAR MEDIUM
FOR THE RAPID DIAGNOSIS OF DIPHTHERIA

By Leslie Hoyle M B Leeds
OXLEY RESEARCH FELLOW UNIVERSITY OF LEEDS

(From the Emergency Public Health Laboratory (Medical Research Council), Cardiff, and the Cardiff and County Public Health Laboratory)

SINCE the discovery by Anderson and others (1931) of the diphtheria types a wide variety of tellurite media have been introduced for diagnosis and type differentiation and some apology may be necessary for the description of yet another such medium However, the multiplicity of the media in common use is in itself an indication that a really satisfactory medium has yet to be found Growth is slow on most of these media none of which consistently fulfils the requirements of the clinician in regard to speed of diagnosis The medium described here is advanced as a solution to this problem

Cooper and his co-workers at Leeds (1940) have recently made a comparative study of most of the media in common use, and have recommended Neill's medium (Neill 1937) as the most satisfactory, since it was easy to prepare and give the highest percentage of positives of all the media tried The relative value of the various media in regard to speed of diagnosis was not referred to in the paper, but I understand that little difference in speed was found Neill's medium was introduced for diphtheria diagnosis in Cardiff but its performance was poor—the type of mitis strain prevalent in the Cardiff area either failed completely to grow on the medium or was much inhibited In addition, some of the intermediate strains gave rather slow growth The type of diphtheria prevalent in Cardiff differs from that in Leeds in that gravis strains are rare An analysis of some 200 positives gave the following incidence of the three types intermediate, 59 2% , mitis, 39 2%, gravis, 1 6%

Attempts were made to overcome the inhibitory effect of Neill's medium on mitis strains, and it was found that if the medium was made up as an unheated, instead of a heated, blood agar the effect disappeared The Leeds workers had found that if McLeod's medium was made up as an unheated blood agar the proportion of mitis positives was increased by 6%, but they rejected the unheated blood medium because the type-differentiation was less pronounced Glass (1939) first described the inhibitory effect of heated blood on mitis strains and recommended the use of unheated blood

As a result of much experiment the following medium has been adopted for routine diphtheria diagnosis in Cardiff It bears little relation to the Neill's medium from which it was derived except that the agar basis is the same

℞ Lab Lemco	10 g
Difco proteose peptone or Bacteriological Peptone (Evans Sons Lescher and Webb)	10 g
Sodium chloride	5 g
Agar	20 g
Water	to 1000 ml

Adjust to pH 7 8 and autoclave The agar is best distributed in 200, 400, or 600 ml flasks Other ingredients of the medium are sterile horse blood (B W and Co) laked by freezing and thawing , and a solution containing 0 7 g of potassium tellurite to 20 ml of water (this should be kept tightly corked in the dark)

To prepare for use take 200 ml of agar melted and cooled to 50° C (the temperature being measured by a thermometer immersed in the agar), add 2 ml of tellurite solution and 10 ml of laked blood and pour plates The medium should have a wine-red colour, and acquire a mahogany colour on incubation Spectroscopic examinations made by Dr John Pryde showed that this change in colour is due to a partial conversion of oxyhæmoglobin into methæmoglobin Some difficulty may be experienced in the successful laking of blood by freezing and thawing The following methods have given best results (1) Freeze the blood hard in a mixture of ice and salt for about an hour in the refrigerator, and then thaw in a water bath at 37° C Do not shake the blood either during freezing or during thawing One freezing is usually enough but it may occasionally be necessary to repeat (2) Distribute the blood in screw capped bottles which should not be more than half full and place them horizontally in the freezing element of the refrigerator and leave overnight Thaw out next morning and repeat daily until completely laked Two freezings are usually enough Laked blood is best stored in the frozen state when it will keep indefinitely (3) If facilities for freezing are not available the blood may be laked by addition of sterile distilled water either to the whole blood, or better to the red cells after centrifuging About 1½ volumes of water is needed to lake whole blood This method is not recommended where facilities for freezing are available as it introduces undesirable dilution of the blood

PROPERTIES OF THE MEDIUM

The medium gives very rapid growth of all types of *Corynebacterium diphtheriæ*, and diagnosis is always possible after 18 hours' incubation Plates should be examined between 18 and 20 hours after inoculation The morphology of *C diphtheriæ* is not seriously modified by the medium, so that in cases of doubt diagnosis can be made by examining gentian-violet stained films from the tellurite, the diphtheria bacilli showing a typical appearance Neisser-stained films are less satisfactory The selectivity is good and the medium will stand heavy inoculation In particular *C hofmannii* grows much less vigorously than on most tellurite media and *C diphtheriæ* will hold its own on the medium against any other organism except *C xerosis* As a result of these properties it is quite feasible when examining large numbers of contacts to inoculate four or six swabs on one plate without any attempt at spreading This method however should not be used until the worker has had some experience of the medium and is familiar with the morphological appearances of *C diphtheriæ* on it Ear swabs should always be carefully spread

Type-differentiation, while inferior to that given by McLeod's medium or by Neill's, is sufficiently good to present no difficulty to anyone with experience of tellurite media The most characteristic feature of *C diphtheriæ* on the medium is the grey colour of the colonies, and plates should be first examined with the naked eye to pick up grey colonies which may then be examined with a hand lens to determine the type Prof H D Wright recommends the use of a binocular dissecting microscope in examining the plates When using this method I find that the best results are given if the plate is placed on an opaque stage, the colonies being illuminated from above by daylight Transmitted light is much less useful The characters of the growths commonly encountered on the medium after 18 hours incubation are —

C diphtheriæ (gravis) —Grey colonies, 1 5–2 5 mm in diameter, with a dull matt surface May be slightly umbonate and show indented margins Colony can be pushed along the surface of the medium with a loop

C diphtheriæ (mitis) —Grey colonies, 1 5–2 mm in diameter, with regular margins and a shining surface Variation in the size of colonies is common

C diphtheriæ (intermedius) —Small grey colonies 0 5–0 75 mm in diameter with shining surface Centre of colony is darker than the periphery, and colonies are very uniform in size

C hofmanni —Usually shows small, rounded, white or greyish white colonies 0 5–0 75 mm in diameter If the medium has been freshly prepared or if the blood is incompletely laked the growth is more profuse, colonies attaining 1 mm in diameter In these cases the colonies are black in the more heavily inoculated areas and white when well isolated

C xerosis —Black, shining colonies of variable size

Streptococci —Minute black or brownish black colonies

Others —Occasionally gram negative cocci, yeasts, and sarcinæ have been encountered and may present some difficulty, the colonies resemble the intermediate type of *C diphtheriæ* but are larger Certain sporing aerobes may grow and give brownish mucoid colonies

VARIATIONS OF THE MEDIUM

Experiments have been made, as follows to determine how far the formula given above can be altered without the medium losing its characters —

The sterile laked horse blood may be replaced by ox or sheep blood, but ox blood laked by Neill's method (addition of formalin and ether) is unsatisfactory Human blood is somewhat inferior to horse blood

The amount of laked blood may be varied from 3 to 5% If more than 5% is used the medium becomes so dark that it is not easy to distinguish the colour of the colonies With less than 3% of blood the medium becomes less selective

The blood must be completely laked If unlaked or partially laked blood is used the growth is more profuse but the selectivity is much less good and the type differentiation is very poor

The concentration of tellurite can be varied within fairly wide limits, but a final concentration of 1 3000 gives best results

The medium appears to owe its characteristic properties mainly to the agar basis This cannot be replaced by ordinary nutrient agar, or by Hartley digest agar Lab Lemco must be used and not ordinary Lemco

It was at first thought that the use of Difco proteose peptone was essential, other peptones tried having given very inferior results, but Professor Wright informed me that Bacteriological Peptone (Evans Sons, Lescher and Webb) gave the same results I was able to confirm this, but if Evans's peptone is used it is important to use a sample of recent manufacture

Experiments were also done using CCY agar as basis (Gladstone and Fildes 1940) Rapid growth of *C diphtheriæ* was obtained but the medium was less selective than mine and the growth of the intermediate type of *C diphtheriæ* was inferior, though the CCY medium gave more profuse and rapid growth of *C diphtheriæ* (mitis)

RESULTS

When the medium was first introduced it was carefully compared with serum and gave the following results —

Total number of swabs examined	1824
Total positive	464
Positive on serum	378 (81 5%)
Positive on tellurite at 18 hours	462 (99 6%)

Two strains did not appear on the tellurite Both grew readily when subcultured from the serum, and the failure in those instances was probably due to faulty inoculation It is to be noted that the serum slopes were inoculated first

The proportion of serum positives to tellurite positives has been higher than that found by the Leeds workers (81 5% compared with 70%) This is probably due to two factors First, in Cardiff duplicate films are made from the serum, one being stained by Neisser and one by Gram, these are examined by independent workers and then cross-checked, and as a result the serum positives are about 10% higher than they would be if only Neisser-stained films were examined Secondly, the types of diphtheria bacilli isolated in Cardiff, being almost entirely intermediate and mitis, are easier to recognise on serum than the gravis type prevalent in Leeds

DISCUSSION

The medium has now been in use for some eight months in three different laboratories A number of different technicians have made it with identical and consistent results, and workers with wide experience of tellurite media and others new to such media have been able to use it with success The main value of the medium is in the rapidity with which diagnosis can be made The rate of growth is almost as good as on serum and the number of positives found at 18 hours is far greater than on serum This fact, coupled with the fact that diagnostic films can be made direct from the tellurite in doubtful cases, raises the question as to whether the use of serum might be discontinued I have not so far had the courage to abandon the serum entirely, but it is clear from these results that if serum were given up only about 1 positive in 200 would be missed, and it is doubtful if the time and labour involved in the use of serum is worth while for such a small increase in accuracy

It is probably unwise to recommend any one medium for general use in diphtheria diagnosis since the problems presented to the bacteriologist vary very much in different areas The observations of the Leeds workers, extending over many years, seem to leave no doubt that where gravis strains are predominant the heated blood media such as McLeod's and Neill's are the media of choice, since they seem to be better for picking out scanty gravis colonies than other media These media, however, do not seem to be satisfactory in areas such as Cardiff where hæmatin-sensitive mitis and slow-growing intermediate strains are common The medium described here will be found most valuable where slow growing strains are common, and especially where the intermediate is the predominant type

SUMMARY

A tellurite blood-agar medium is described with which *diphtheria diagnosis can be made in 18 hours*

Of 464 consecutive positive swabs examined, 462 were positive on the tellurite at 18 hours, and 378 positive on serum

The type differentiation with this medium, while inferior to certain other tellurite media, is sufficiently good to present no serious difficulty to experienced workers

I wish to thank Prof J W McLeod and Prof H D Wright for helpful suggestions, and Dr J Pryde for spectroscopic observations on the medium

BERI-BERI HEART IN A YOUNG WOMAN

BY JOAH BATES, M B Lond, D C H, D P M
HOUSE PHYSICIAN AT ADDENBROOKE'S HOSPITAL, CAMBRIDGE

A WOMAN of 22 was admitted to Addenbrooke's Hospital on June 12, 1940, under the care of Prof J A Ryle She complained of breathlessness on exertion and weakness for the past 6 months, with amenorrhœa There had been no hæmorrhage of any kind She had been up and about until a week before admission, though feeling tired and unfit She was pale and thin, with a considerable brown pigmentation of skin and mucous membranes The scalp was covered with neglected septic lesions There was œdema of the lumbar region and also of the ankles Tendon reflexes were absent at first but returned later She was orthopnœic but not cyanosed The veins in the neck were distended and pulsating The liver was enlarged and tender but the spleen was not palpable The heart was enlarged to left and right, there was definite triple rhythm, an apical systolic murmur, and the blood-pressure was 90/50 Pulse-rate about 110, temperature varied between 97° and 101° Blood-count red cells 1,370,000, Hb 14%, white cells 11,400 (polymorphs 83%) Blood Wassermann reaction negative, blood-urea 32 mg per 100 c cm, blood-potassium 16 5 mg per 100 c cm, serum proteins 5 4 g per 100 c cm (albumin 3 8, globulin 1 5) Vitamin-B_1 excretion test showed considerable deficiency The urine contained albumin and large numbers of pus cells with *Bacillus coli*

The advanced cardiac failure, anæmia, pyrexia and cafe-au-lait pigmentation at first suggested bacterial endocarditis but there was no evidence of embolism or valvular disease The pigmentation of exposed parts and inside the mouth, together with the low blood-pressure, suggested Addison's disease, but this would not have explained the gross anæmia and heart failure, and there was no vomiting The final diagnosis of beri-beri heart was made because the B_1 excretion was only a sixth or less of the normal and was not increased by a test dose of vitamin B_1

The patient was treated with vitamin B_1 (diet and concentrate) and iron in large doses, she was also given a few doses of suprarenal cortical extract The œdema had disappeared in a fortnight and the condition steadily improved until her discharge on Aug 10 Her husband a labourer, had been away for some months on war service and the patient, though not obviously depressed, had been refusing to eat or to meet her friends This may have been a schizophrenic episode, though a doctor was not called in until her condition looked desperate During the development of her illness her diet probably contained an unduly high proportion of carbohydrate This may help to explain both the anæmia and the production of symptoms of thiamin deficiency She had done quite well at school so could hardly be regarded as mentally deficient Her mental state improved considerably while in hospital, though she remained rather apathetic There was a gain of 1½ st in weight and her hæmoglobin was 90% on discharge

---

DETERMINATION OF BLOOD-VOLUME IN SHOCKED PATIENTS

By D K Hill, B A *

FELLOW OF TRINITY COLLEGE CAMBRIDGE PHYSIOLOGIST IN THE DEPARTMENT OF MEDICINE BRITISH POSTGRADUATE MEDICAL SCHOOL

In the stress of emergency after the admission of air-raid casualties to hospital there is little time and not much justification for procedures which are not primarily therapeutic For this reason the labile condition of secondary shock receives only such investigation as can be fitted in appropriately with the recognised treatment of the patient Measurement of the circulating blood-volume by existing methods is either considered dangerous or involves a technique too elaborate and lengthy for use on a patient in such a precarious state The method of determining the circulating blood-volume described here combines accuracy and simplicity with benefit to the patient

A known quantity of blood of hæmoglobin concentration different from that of the recipient's blood is infused intravenously The change in hæmoglobin concentration of the recipient's blood is measured, and the blood-volume before infusion can then be calculated as follows —

Equate total hæmoglobin before and after infusion of x c cm of blood

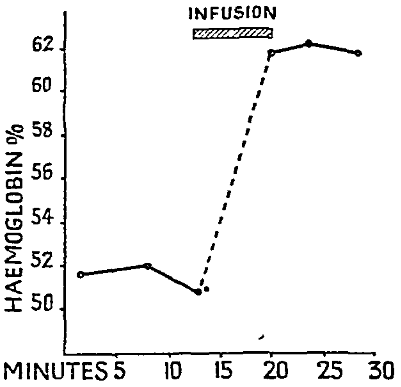
Let BV_x = initial blood volume,
Hb_1 = hæmoglobin concentration of patient's blood before infusion,
Hb_2 = hæmoglobin concentration of infused blood,
Hb_3 = hæmoglobin concentration of patient's blood after infusion

Before Hb in patient $= BV_x \times Hb_1$
Hb in bottle $= x \times Hb$
After Hb in patient $= (BV_x + x) \times Hb_3$

$$(BV_x \times Hb_1) + (x \times Hb_2) = (B_xV_x + x) \times Hb_3$$

$$BV_x = \frac{x(Hb_2 - Hb_3)}{(Hb_1 + Hb_3)}$$

Blood with a hæmoglobin concentration considerably higher than that of the patient was obtained from stored blood by removing the plasma The infusion should be rapid and for this reason air-pressure drive is required Drip transfusion is too slow with a fluid so rich in corpuscles Hæmoglobinometry has been accurately done by a photoelectric method using 20 c mm of blood obtained from a deep stab in the lobe of the ear It is essential to have a free flow of blood so that squeezing can be avoided Samples are taken at short intervals before and after infusion and sampling and observational errors are thereby made insignificant



Case 1 —Hæmoglobin concentration before and after infusion of 400 c cm blood

RESULTS

Case 1 —Boy aged 16 Liver ruptured by lorry wheel Hæmorrhagic shock after operation Blood pressure 60 mm Hg Pulse rate 140 The hæmoglobin concentrations over the period of infusion, expressed as percentages on the Haldane scale, are shown in the figure

Hb concentration of 400 c cm added blood = 95 7%
Hb concentration of patient's blood before infusion = 51 3%
Hb concentration of patient's blood after infusion = 61 8%
Calculated blood volume = 1 29 litres

Case 2 —Woman aged 55 Air raid casualty, shocked after severe injury to limbs Blood pressure 40 mm Hg Pulse imperceptible Subsequently died

Hb concentration of 330 c cm added blood = 109%
Hb concentration of patient's blood before infusion = 68 5%
Hb concentration of patient's blood after infusion = 78 8%
Calculated blood volume = 975 c cm

Case 3 —Man aged 35 Blood pressure 110 mm Hg Pulse rate 100 Hæmatemesis 2 days previously

Hb concentration of 540 c cm added blood = 118 7%
Hb concentration of patient's blood before infusion = 32 7%
Hb concentration of patient's blood after infusion = 46 2%
Calculated blood volume = 2 9 litres

Case 4 —Man aged 52 Hæmatemesis a week previously Blood pressure 118 mm Hg Pulse rate 88

Hb concentration of 500 c cm added blood = 81%
Hb concentration of patient's blood before infusion = 21 6%
Hb concentration of patient's blood after infusion = 27 0%
Calculated blood volume = 5 0 litres

Case 5 —Man aged 50 Slow hæmorrhage over long period from gastric ulcer Blood pressure 124 mm Hg Pulse rate 80

Hb concentration of 420 c cm added blood = 100 3%
Hb concentration of patient's blood before infusion = 22 7%
Hb concentration of patient's blood after infusion = 30 1%
Calculated blood volume = 4 6 litres

The blood-volume is inversely proportional to the change in the patient's hæmoglobin concentration but since the change is small the error in measurement of blood-volume is almost the same as the error in measurement of the change of hæmoglobin concentration In case 1 the accuracy (as judged from the scatter of points in the figure and neglecting other less important sources of error) is of the order ± 200 c cm

---

* In receipt of a grant from the Medical Research Council

DISCUSSION

This method for determining circulating blood-volume has the same rationale as the commonly employed dye method but is more reliable since the added "dye" (hæmoglobin in corpuscles) cannot escape from the circulation. The method can be used with benefit to the patient in circumstances when determination of blood-volume by other means would not be justifiable, provided the hæmoglobin concentration of the added blood differs sufficiently from the initial hæmoglobin value in the patient. The method was used in two severely collapsed patients and the circulating blood-volume was found to be exceedingly low.

Bushby, Kekwick and Whitby[1] have suggested a method of finding blood-volume by observing the dilution of hæmoglobin consequent on infusion of plasma. We have used such a method in a number of cases with hæmorrhagic or traumatic shock. Considerable inaccuracies, especially in shocked patients, due to loss from the circulation of the infused fluid, may limit the value of results so obtained, unless, as Whitby and his colleagues insist, the observations are carried out immediately before and immediately after the rapid transfusion of a known volume of plasma. Hæmoglobinometry done frequently shows that about 40% of the dilution acquired after rapid infusion may be lost within 30 min. This is probably due to the fact that plasma- or serum saline, being diluted with saline anticoagulant, has a protein content only 60–70% normal. An approximate correction for loss of fluid during infusion may be made by the construction of a curve of hæmoglobin values and extrapolation. The method might be improved by the use of serum from coagulated blood not diluted with saline.

SUMMARY

Blood-volume can be determined while treatment is being given to a shocked patient by observing the change in hæmoglobin concentration after infusion of a known quantity of blood from which the plasma has been removed.

We thank Mr. A. C. Pincock for technical assistance and the chief medical officer of the L.C.C. for permission to use observations made on patients in Hammersmith Hospital.

Medical Societies

ROYAL SOCIETY OF MEDICINE

At a meeting of the section of Medicine on Jan. 28, with Sir MAURICE CASSIDY, the president, in the chair, a discussion on the therapeutic value of

Transfusions of Derivatives of Blood

was opened by Colonel LIONEL WHITBY. He said that transfusion should always be performed with a definite object—restoration of oxygen-carrying capacity, for which red cells are essential, as in the anæmias; or restoration of blood volume, for which any innocuous fluid which is well retained in the circulation is suitable. On rare occasions transfusion is used to contribute leucocytes, platelets, clotting elements, complement or antibodies. Blood derivatives are as a rule very efficient for restoring blood volume, but with the exception of stored blood are useless for increasing oxygen-carrying capacity. Including stored blood, they are useless for contributing leucocytes and serological constituents. The available derivatives are stored blood of different ages, citrated plasma, blood-serum, dried blood-serum and concentrated suspensions of red cells in physiological glucose-saline or plasma. Stored blood a few days old, cleanly and properly taken, is almost as good as fresh blood for restoring oxygen-carrying capacity. Its corpuscles are sufficiently durable to allow decantation from and re-suspension in saline or glucose-saline in high concentration. With time, the corpuscles deteriorate and may become fragile and hæmolysed. Such corpuscles do not endure long in the circulation and produce a reaction. They contribute only temporarily to the oxygen-carrying power, and are unsuitable in the anæmias. French physicians, however, have used ageing blood somewhat daringly as a means of introducing iron into the circulation, and even aged blood is useful in the emergencies of battle. Carefully-taken and refrigerated blood, to which glucose has been added, does not lose its volume-restoring properties for four weeks. When it is under a week old its oxygen-carrying power is almost equivalent to that of fresh blood. The younger the blood the greater its durability. The disadvantage of stored blood is the complexity of the apparatus required for its proper preservation. The corpuscles of young stored blood and fresh blood can be used for the preparation of concentrated red-cell suspensions for the treatment of anæmia, where the object is to produce the maximum oxygen-carrying power. Such suspensions allow an increase of hæmoglobin of approximately 20% per pint, instead of the 10% of the ordinary transfusion. In six cases the results have been excellent. The procedure is particularly advantageous in cases of true plastic anæmia leading a transfusion life, and greatly reduces the time needed for the transfusion.

Experimental work on cats (which Colonel Whitby illustrated by slides) has shown the relative properties of the various derivatives and substitutes. The effect of saline is evanescent. Respiratory embarrassment is associated with transfusion of substitute fluid but is most marked with serum. The best replacement substance, and the one adopted by the Army, is plasma saline. For maintaining as well as restoring blood pressure a protein-containing substance is necessary. A 25% hæmoglobin-Ringer solution is quite efficient for restoring and maintaining blood volume, but has the grave disadvantage that hæmoglobin is a foreign pigment and has to be excreted. Gum-saline is reasonably efficient for maintaining blood-pressure, but it is difficult to make two suspensions alike. Glucose is as evanescent in its effect as saline. The order of preference is whole blood, plasma, serum, hæmoglobin-Ringer, gum saline, isotonic saline and isotonic glucose. The only true index of the efficiency of plasma is its protein content, because the crystalloids are rapidly excreted. The plasma produced by the Army transfusion service has a protein content of 4–5%. In the treatment of over 100 air-raid casualties, 165 pints of plasma were used, and only 3 patients had mild and transient rigors. The plasma was anything up to 56 days old, and was stored in a cool room in the dark. The maximum amount given to any one case was six pints. In large transfusions it is an advantage for at least one pint in three to be blood. Army citrated plasma contains no Merthiolate preservative. Its utility for blood loss is unequivocal. Its use must be controlled by serial blood pressure examinations. For any proper assessment of the relative value of plasma and serum, cases that have suffered comparable blood loss and comparable reduction in blood-pressure must be systematically studied throughout the transfusions, or no-one can say whether the restoration of blood-volume had been adequate, inadequate or excessive. The rise of blood-pressure that can be expected from each pint transfused is between 10 and 20 mm. Hg. The commonest cause of failure of the blood-pressure to rise quantitatively with transfusion is continued bleeding. The need for transfusion rarely ends in the resuscitation ward; the patient should be sent to the theatre with a cannula tied in a bottle of slowly-dripping blood which can be instantly accelerated if the occasion arises.

Dr. JANET VAUGHAN analysed the work of the North West London Blood-supply Depot. Concentrated red cells, she said, are useful when it is necessary to raise the protein content without affecting the blood-volume. In assessing relative therapeutic value, relative toxicity and dosage must be considered as well as therapeutic effect; after these considerations came ease of preparation, transit and storage. Unfiltered, filtered and dried plasma and filtered, dried and citrated serum are available, but only the first two groups of plasma and serum respectively have been used in the depot. Unfiltered plasma is obtained by siphoning from sedimented red cells, preferably after five days, and not later than two weeks Its protein content is 4–5% It very rarely forms clots Filtered plasma is clear but very apt to clot Merthiolate 1% has been added habitually to plasma to prevent infection , but disinfectant is not added to the sera, as the risk is much less Filtered serum contains about 7% of protein No serious reactions have followed the use of any of the preparations Unfiltered plasma has been given to 18 air-raid and 7 civilian casualties, with two reactions of mild fever and rigor Filtered plasma has been given to three times as many cases again with only two reactions With filtered serum 19 bottles have provoked two reactions in one case the serum was given cold, which was inadvisable With dried serum 47 infusions have produced 13 reactions most of them very trifling and following highly concentrated injections , at normal concentrations the incidence of reactions falls considerably Plasma serum and blood in all the forms seem equally effective, as far as it is possible to assess them under blitz conditions, and there is no great difference in the dosage Fresh blood should be given if severe sepsis is present The only sure guide at present to therapeutic value is the rise of blood-pressure , the pulse is very unreliable Since some anæmia has been found in most air-raid casualties both blood and a protein fluid seem indicated With unfiltered plasma there have been 23 good results and 6 deaths · with filtered plasma the figures are 84 and 12 Blood has been given to 30 patients successfully and to 7 who have died An initial dose of 400 c cm of normal serum is satisfactory in most shocked patients Concentrated doses do to some extent withdraw fluid from the tissues into the blood-stream and improve blood-volume, but better results are obtained with normal serum Hæmoglobin values of 60–70% are often found in air-raid casualties Probably it is best to transfuse with one or two bottles of plasma and then with one or two bottles of blood , 37 patients treated in this way have done extremely well As far as possible, therapy should be controlled by blood-pressure and hæmoglobin reading Burns should be treated by transfusion immediately Transfusion is too often delayed for 24 hours or until after " cleaning up ' it should start before arrival in the theatre and continue all through surgical intervention and into the ward—for 24–48 hours If protein fluid continues to drain from the patient transfusion must go on still longer fresh blood being used for choice Plasma or serum are better than blood during the first 24 hours after burns, when hæmoconcentration occurs Concentrated serum will reduce local œdema but has proved disappointing in nephrotic œdema Dried serum has the advantages that it does not clot, is not readily infected is unaffected by temperature, is small in bulk Plasma seems to be an ideal culture medium the infection-rate is 7% even under the most rigorous conditions There is at present no proof that its fibrinogen is important Concentrated red cells have become almost embarrassingly popular ; they are valuable for aplastic anæmia, anæmia associated with sepsis and anæmia in elderly patients requiring immediate operation Red cells should not be used younger than five days or older than a fortnight They last well in the circulation except in a small group of splenomegalic anæmias Two bottles will raise the hæmoglobin level from 20 to 60%

Dr **Helen Brown** said they have been unable to confirm the work of Aldrich on nephrosis , there was increased albuminuria after injection, so presumably the protein was excreted In one case the blood protein rose for 24 hours only, and the œdema became worse

Prof T B **Davie** wondered whether cases of anæmia with sepsis should have concentrated red cells or fresh whole blood His practice has been to give whole blood to raise the hæmoglobin to 90% as soon as possible and thereafter to maintain this level by repeated injections of fresh whole blood from donors In drawing blood for blood banks plasma is made available automatically but bleeding for serum would produce difficulties

Mr **George Qvist** related the cases of two firemen with second-degree burns of the hands and face with severe blistering There was no real shock and blood-pressures were about 130 The burns were cleaned up and treated with continuous saline Next morning, one was doing well and the other showed a severe fall of blood-pressure and a hæmoglobin of 132, with severe œdema of hands and face He was given repeated infusions of concentrated serum—about 620 c cm. of four-times concentrated—and each time the blood-pressure stayed up for about half an hour In 24 hours however the anxiety was at an end The case illustrated Dr. Vaughan s statement that all burns should be treated with transfusion straightaway

Dr **Montague Maizels** agreed that serum may be theoretically better, but plasma from blood banks has much to recommend it and infection is not a serious factor A separate outfit should be used for each bottle to avoid transferring infection which can then be cut down to 5, or even 2% Merthiolate is an absolute snare it obscures the issue Unfiltered plasma being cloudy, makes detection of infection more difficult, but filtered plasma is a beautifully clear fluid and as long as it is translucent it is pretty surely not infected

Dr P L **Mollison** said that there is a distinct disadvantage in having a suspension containing more than 7½ million red cells in concentrated preparations since they then become too viscous to flow

Colonel **Whitby** in reply, said that treatment of secondary shock is an entirely individual matter. He agreed that merthiolate is a snare —Dr **Vaughan** also briefly replied

Reviews of Books

Industrial Hygiene

By A J **Lanza**, M.D , assistant medical director, Metropolitan Life Insurance Co , New York , and **Jacob A Goldberg**, Ph.D , secretary, Industrial Hygiene Committee, New York Tuberculosis and Health Association. London Humphrey Milford, Oxford University Press Pp 743 42s

The interest taken in industrial medicine and hygiene had been growing steadily during peace-time, but a sudden fillip has been given to it by the war More medical men are being appointed to look after the health of factory workers and they are meeting problems which differ in many respects from those of ordinary medical practice A real need has arisen for an up-to-date and authoritative textbook on the subject and since a complete survey appears to be beyond the scope of one individual the ideal textbook on industrial medicine should be the work of a team of experts The many facets of the work are well shown in this new book on industrial hygiene from the United States It deals almost entirely with American industrial conditions which differ in many respects from ours It will have a limited value for British readers but should not be neglected on that account Its 21 chapters include a good one by Selby on the scope and organisation of health services in industry, and Woodruff deals adequately with the physical examinations of employees Weeks contributes a useful section on the care of the eyes in industry and Bowman writes about the mental hygiene of factory workers Other chapters cover traumatic surgery (Moorhead and Slattery), physical therapy (Bierman) ; rehabilitation of the injured worker (Kessler) ; silicosis and asbestosis (Lanza), skin diseases (Schwartz) industrial poisoning by the heavy metals (Reznikoff) and by gases and fumes (von Oettingen and Sayers) , lighting and atmospheric control (McConnell) ; and the place of the nurse in industry (Rosamund Goldberg) J Burns Amberson's chapter on tuberculosis and other pulmonary diseases is a concise account which would take a place of honour in a textbook of medicine Wright s chapter on peripheral vascular disease is made valuable by its relevant case-histories and Foster Kennedy's article on the nervous conditions resulting from injury sparkles with erudition humour and wisdom The editors are to be congratulated on having cast such a wide net but some of the catch might have been thrown back into the sea Lanza's own chapter on silicosis and asbestosis is one of the shortest in the book and might well be expanded in the next edition , whereas those sections written by contributors who have had little contact with industry could be shortened to make a more balanced book

Outlines of Industrial Medical Practice

By HOWARD E COLLIER, M D Edin , formerly reader in industrial hygiene and medicine, University of Birmingham London Edward Arnold and Co Pp 440 21s

Dr Collier has made a valiant attempt to cover the field of industrial medicine , in five main sections he deals with the executive and advisory functions of the works doctor, industrial psychology, industrial medicine, and industrial forensic medicine He insists, quite properly, that the book is only an outline , but it would have been better to omit all reference to the safety provisions of the Factories Act 1937 unless he had been prepared to deal with them fully , over-compression has given an erroneous idea of the requirements of Part II It is just as important for the works doctor to know about such matters as air receivers, steam boilers cranes and hoists as that he should be told that a fixed vessel containing boiling or corrosive liquid should be covered or have a guarding rail three feet high And in the description of the duties of the examining surgeon the Home Office instructions quoted are those of 1933, the important changes made by the 1937 act being ignored The chapter on accidents and safety is inadequate even in an outline and two of its six pages are given up to accidents in sewers, rather a far cry from factory experience The section on the keeping of health records will be of more use to the works medical officer than the lavish space devoted to the psychology of the individual and the group Some of the rather numerous inaccuracies may be due to careless proof-reading, as for example the statement that good results in the treatment of carbon-monoxide poisoning are obtained from the use of 93% CO_2 and 7% O_2, but not the failure to mention the Mark IV dust respirator while recommending less efficient types And the lapses are the more to be regretted as the work is logically planned and well set out

Health and Efficiency of Munition Workers

By H M VERNON, D M Oxfd, formerly investigator for the Health of Munition Workers Committee and for the Industrial Health Research Board London Humphrey Milford, Oxford University Press Pp 138 *8s 6d*

Dr Vernon's pioneer investigations have often been referred to in these columns He has shown that many munition workers suffered from sickness and loss of efficiency owing to unfavourable conditions and long hours of work It is not likely that the errors committed during the last war will be repeated in so gross a form during the present one, but some of the lessons learned will probably be forgotten or ignored Dr Vernon has therefore thought it worth while to recapitulate briefly in book form the evidence collected by the committee and the remedies which were then suggested Although the book contains no new work and nothing which cannot be found in Dr Vernon's articles and larger books, or in the publications of the Industrial Health Research Board it is to be recommended to works doctors and factory managers on account of its handy size and its concise and accurate presentation of the subject matter

Synopsis of the Principles of Surgery

By JACOB K BERMAN, M D , F A C S , assistant professor of surgery, Indiana University school of medicine, Indianapolis London Henry Kimpton Pp 615 *25s*

SOUND surgery is built on anatomy and physiology, pathology and common sense, and a good textbook must observe the fundamentals if it is to have a right perspective Judged by these standards Dr Berman's book is fairly successful The strong emphasis on physiology will be appreciated by the student fresh from his preclinical course for it forms a natural link between the laboratory and the bedside The general arrangement of the book is not out of the ordinary After a short historical review there are chapters on pathology, bacteriology and general surgical subjects Then follow three chapters on the constitutional factor, the interchange of body fluids and the acid-base balance, subjects which often receive scant attention in surgical textbooks The remaining chapters cover the field of surgery as applied to the various systems of the body The general problems of burns are well presented but the discussion of treatment is not so good, and Dr Berman's statements about blood-transfusion, continuous immersion, and the incidence of suppuration under tannic-acid crusts are open to question There are many footnotes in which special points are elaborated, illustrated and discussed, the continuity of the main text being thus uninterrupted Diagrams and photographs are plentiful and on the whole excellent, and there are numerous references

Medical Electricity for Massage Students

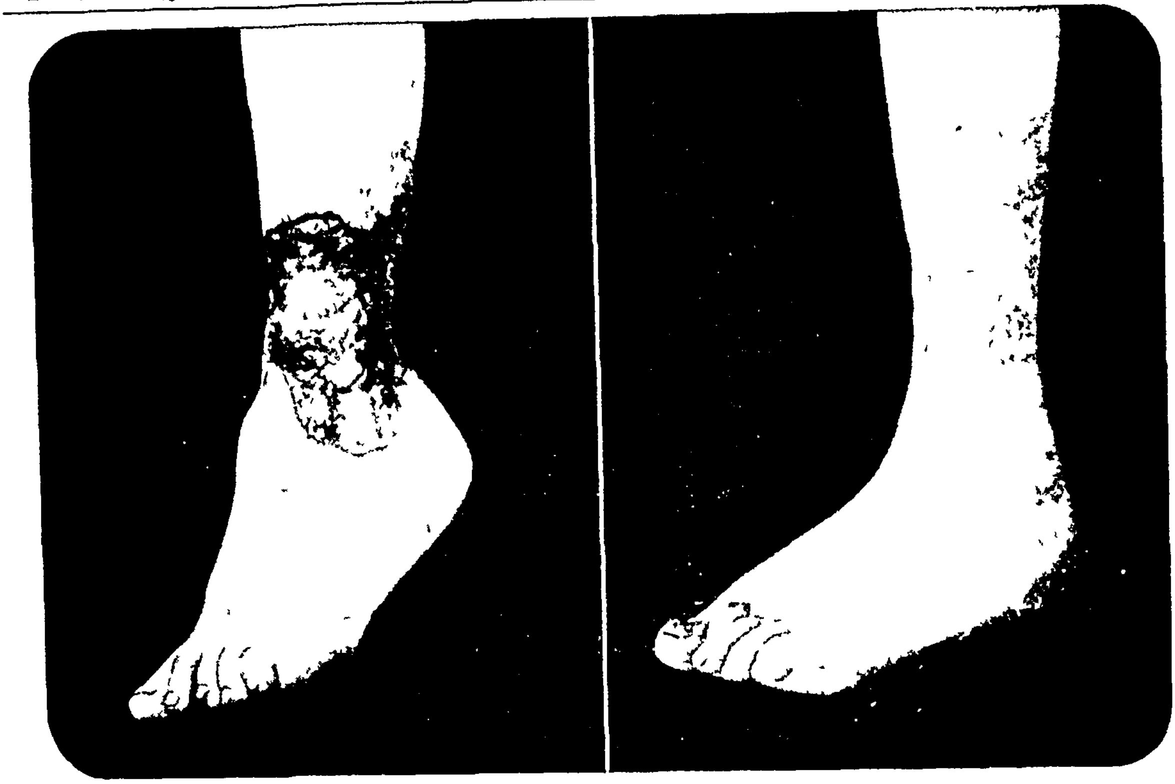
(2nd ed) By HUGH MORRIS, M D Belf , D M R E London J and A Churchill Pp 394 18s

IN the new edition of his book, which will continue to be of great use to the massage student for examination purposes, Dr Morris gives a workmanlike summary of the subject, and provides a good practical foundation for the use of medical electricity He explains well established facts without unnecessary and confusing theorising The description of apparatus, and the practical details for the application of treatment are good Ultraviolet-light treatment is fully described, diathermy and short- and long-wave therapy more briefly A chapter on diseases and their treatment he admits to be less detailed than might be wished but in a work of this size it is not possible to describe all the uses of medical electricity The value of the various treatments is fairly assessed A useful glossary and a good index are included

Modern Diagnosis

Edited by SIR HUMPHRY ROLLESTON, Bt , M D , F R C P, and ALAN A MONCRIEFF, M D , F R C P London Eyre and Spottiswoode Pp 286 *12s 6d*

THIS is the fifth of the Practitioner Handbooks and consists of a number of recent contributions to the *Practitioner*, reprinted, revised, and supplemented by one or two new chapters The first nine articles are on purely clinical subjects, such as the tongue, the nails, pain in various situations, swellings and sinuses in the neck in childhood , the other eleven are on laboratory subjects The contributors are all well-known authorities, and their aim is to remind and inform the general practitioner in simple practical style The clinical articles are the more successful , all are good, and those on abdominal pain by Mr W H Ogilvie and on cervical swellings and sinuses in children by Mr Charles Donald specially so The laboratory articles discuss both those procedures which the practitioner may reasonably be expected to undertake himself (though here it is curious that the benzidine reaction for occult blood in stools is omitted), and those which he may wish to understand, though their performance is a matter for the trained laboratory worker Here there are some misleading statements Dr S C Dyke and Dr Eileen Harvey state that " a high proportion of sufferers from erythema nodosum give a positive reaction " to a Mantoux test, " thus demonstrating the tuberculous origin of the condition," although they have already explained that a high proportion of healthy subjects, after early childhood, react positively to this test Dr R G Waller points out that the Sonne bacillus is a common cause of dysentery in this country, and " here again the results of bacteriological examination of the stools should be supplemented by agglutination tests of the blood " for diagnostic purposes this advice will lead to little but a waste of time and money On the whole, the laboratory articles are written on the assumption that the practitioner sends material or even the patient to the laboratory for examination, and receives a report That is why, although usually sound, these articles are not entirely satisfactory Except in respect of the simplest and best standardised procedures, the clinician be the practitioner or specialist, seldom knows as well as the pathologist just what examinations are most likely to throw light on a given patient's case, or just what light they do throw in that particular case The aim, therefore, should be personal contact between clinician and pathologist in all but the simplest problems It is difficult to achieve that in present conditions of practice, but short articles such as these are an inadequate substitute for it They rather encourage that penny-in-the-slot pathology which wastes so much of the laboratory's time and the patient's money, and may easily miss the solution of the clinical problem



Varicose Conditions

SUPPORT and Occlusion are fundamental in the treatment of varicose conditions

In the 'Elastoplast' Bandage the combination of the particular adhesive spread, with the remarkable *stretch* and *regain* properties of the 'Elastoplast' cloth, provides the exact degree of compression and grip

The case illustrated above, a patient aged 60, shows an Annular Ulcer of 26 years standing The picture on the right shows the same leg after treatment with 'Elastoplast' only for a period of 12 months

Under ambulatory treatment using 'Elastoplast,' malleolar, gravitational and large or deep-seated ulcers clear up rapidly

'ELASTOPLAST BANDAGES AND PLASTERS ARE MADE BY T J SMITH & NEPHEW LTD, HULL

THE LANCET

LONDON: SATURDAY, FEBRUARY 8, 1941

OVERTIME AND OVERTIRING

WHEN a north-country firm was summoned last month for working boys longer than the law allows the magistrate dismissed the case on the ground that such prosecutions were likely to impair the war effort. The Minister of Supply had given the firm carte-blanche to do as they liked. We have all taken this question of war effort so much to heart that we have forgotten the first principle of conserving energy. It is not the man who digs his garden most violently on the first day of spring who gets his digging done first. Mr. J. H. MIDDLETON has told us before now the story of his too eager uncle whose indulgence in digging led to blistered palms and a sharp attack of lumbago, and this beautiful analogy fits like a glove the case of overtime in industry. It seems incredible that we should be learning again, by experience not precept, the lesson which the last war made so painfully lucid. In 1916 we were told[1] that munition workers had "been allowed to reach a state of reduced efficiency and lowered health that might have been avoided without reduction of output by attention to the details of daily and weekly rest." In 1941 the same criticism holds good in many factories. Employers have not been able to realise, even yet, that working to capacity does not mean working each man, woman and young person for as many hours as he or she can stand at a machine.

The hours worked by women and young people under 18 are controlled by law, and factory inspectors have power to regulate them. The factory department of the Ministry of Labour has set its face against young people between 14 and 16 working more than 48 hours a week at the outside, even where their services make for the smooth running of a team; and this standard was laid down within five months of the outbreak of war.[2] Yet this standard is being overridden in some places, as the court case mentioned above shows. Women too are still being overworked in some industries. The subcommittee on supply services, whose report was presented to Parliament during January by the Select Committee on National Expenditure, found that in Glasgow women were being asked to work in munition factories seven days a week; and that they left home at 6 in the morning and did not get back till 11 at night. Many had to give up industry because it was impossible to run their homes or make domestic purchases. Thus their services, instead of being used economically for the advantage of the country, were lost completely. But on the whole firms have conformed to the department's standard for women and young people. It is upon grown men that the heaviest burden of overtime is falling and the Government has no legal control over the hours they work. That they are suffering under the strain is evident from their own accounts—one of our peripatetic correspondents recorded his conversation with an overtired man last week (p. 157)—and from the subcommittee's finding that the lessons of the last war "seem largely to have been ignored." This despite the Ministry of Labour's circular of July which recommended an immediate reduction to an average of 55 or 56 a week as soon as the necessary labour force had been acquired. After Dunkirk many factories were working 24 hours a day seven days a week. Within two months the effects of strain appeared in the workers, shown by increased sickness and absenteeism. Fatigue was proving, as usual, a cardinal factor in reducing resistance to infection.

Unfortunately the question of overtime is intricately bound up with the interests of the fighting services, the trade-unions, the employers and the workers themselves. The hours worked by men over 18 are regulated mainly by agreement between employers and trade-unions, and most munition workers belong to unions. Both employers and unions prefer that the regulation of hours should be in their hands, the unions because they naturally like their members to be able to earn more by working overtime. The fact that overtime is paid at the rate of time-and-a-half on week-days and double pay on Sundays has made some difficulties. The subcommittee mentioned above found that Sunday labour leads men to take a day off in the middle of the week, when they only lose an ordinary day's pay and earn double pay on Sunday to make up for it. It is difficult to blame them for this; they are human, living is costly, and they realise that they must take a day off each week if their health and output are not to suffer. Wise employers realise that there is a direct relation between long hours and absenteeism. One managing director put it like this: "You want output. I'll give it to you. But please don't try to tell me how it is to be done. I know that if I overwork my men the output will fall." His firm made tanks. In many cases managers have deliberately reduced hours to increase output. The subcommittee found that in the Royal Ordnance factories absenteeism during the summer drive rose from 10 to 15%; in July it was decided to discontinue Sunday labour wherever possible, and often Saturday afternoon labour as well. Time-keeping improved at once and production did not suffer; indeed one factory, after the reduction of hours, set up a new record for a week's production.

On mere economic grounds we cannot afford this extravagance of overtime; it is enough to recall the proof in the last war that abnormal overtime increases cost out of all proportion to the increase in production and the subcommittee are of the opinion that it is having the same effect now. They point out that the Ministry has used its compulsory powers to a very minor extent. They endorse an immediate reduction of hours to the level recommended by the Ministry and they think no undue delicacy should be allowed to interfere with this necessary change. Mr. ARTHUR WOODBURN, who is a member of the subcommittee, said in Parliament last week that efficiency in war and industry depended on Parliament's policy being carried out on personal responsibility. Committees cannot carry things out but persons can. It is up to the firms to see to it that the Ministry's advice is followed. The three-shift system advocated by the subcommittee would safeguard the health of the workers and ensure maximal output.

IRRADEX

MEDICAMENTA VERA
P D & Co

VITAMIN A

Growth-promoting and anti infective vitamin. One teaspoonful of Irradex contains as much vitamin A as a teaspoonful of cod-liver oil

VITAMIN B

Promotes appetite and aids digestion. Stimulates growth in the young. Protects the body from nervous disease, such as beri-beri and pellagra. Increases and maintains body weight. Essential for lactation

VITAMIN D

Increases phosphorus and calcium metabolism and assimilation. Prevents and cures rickets in children. Irradex possesses more than twice the vitamin D potency of B P cod liver oil

IRON AND MANGANESE

Iron has been known for centuries to be valuable in the treatment of anæmias, and modern scientific research entirely confirms this fact. Its association with manganese has also been proved to enhance its value

Each fluid ounce represents —

Vitamin A	*16,500 International units*
Vitamin D	*5,500 International units*
Vitamin B_1	*75 International units*
with Vitamin B_2	
Iron and Ammon Citrate	*4 grs*
Manganese Citrate, Soluble	*$\frac{1}{4}$ gr*

In a palatable base containing Malt Extract

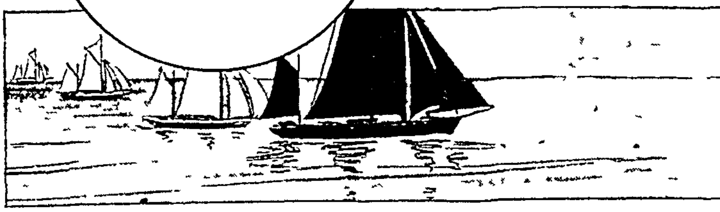
IRRADEX provides the fat-soluble vitamins A and D in a most pleasantly tasting form, far superior to cod-liver oil, the growth-stimulating vitamin B in sufficient quantity, the anti-anaemic effects of iron and manganese, and the nutritive and diastasic value of malt.

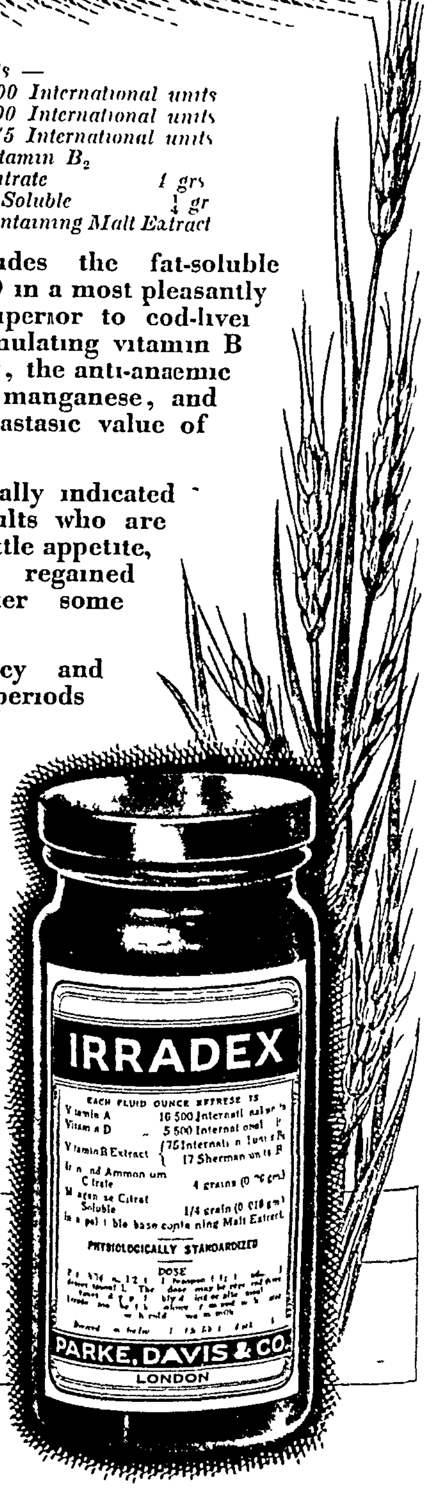
Irradex is specially indicated for children or adults who are underweight, have little appetite, or who have not regained healthy vitality after some acute infection

During pregnancy and lactation, or other periods of stress, Irradex is especially indicated. It may well be prescribed for its nutritive effect in convalescence from operations

DOSAGE From 1 teaspoonful to 1 dessertspoonful three times a day

Supplied in containers of approximately 1 lb, $2\frac{1}{2}$ lbs and 7 lbs





IRRADEX
EACH FLUID OUNCE REPRESENTS
Vitamin A 16 500 International units
Vitamin D 5 500 International units
Vitamin B Extract 75 International units B_1 17 Sherman units B_2
Iron and Ammonium Citrate 4 grains
Manganese Citrate Soluble 1/4 grain
In a palatable base containing Malt Extract
PHYSIOLOGICALLY STANDARDIZED
DOSE

Laboratories Hounslow Middlesex *Inc U S A, Liability Ltd* compounds Usually a tumour forms with considerable regularity at the site of application—a sarcoma if injected, an epithelial tumour if painted on the skin Tumours due even to dimethylaminoazobenzene, however administered have a site of predilection—the liver—in which epithelial tumours appear regularly Other organs are less often affected Kleinenberg and his colleagues have thus succeeded in raising the total incidence of spontaneous tumours in mice by means of liver extract, of producing a great diversity of growths and of raising the incidence of lung adenomata which were already plentiful in the strain The greatest rise followed extracts of livers from cancer bearing patients, but the response of tumour formation was not limited to these It may be argued that all the patients who died without signs of cancer were nevertheless potentially cancerous For this reason children's livers would have provided a better control It is also perhaps worthy of note that the livers from which the extract was derived did not themselves bear tumours during the life of the patient, though, by way of the blood-stream, these livers must have been subject to repeated applications of the hypothetical endogenous carcinogen which later on was extracted from them There are difficulties in accepting it as proved that the livers from cancer-bearing subjects contain in life naturally occurring substances capable of inducing cancer The character of the stock played too great a part in the enormous rise, and the extract lacked specificity It is as though the claim that dibenzanthracene is a carcinogenic agent had been founded on the raised incidence of lung adenomata which it brings about rather than on its local action at the point of application

Some preliminary experiments recorded by de Ligneris[4] show again some lack of specificity in response to extract derived from cancerous livers Papillomas and a few carcinomas followed skin painting with extracts from both cancerous and non cancerous Bantu livers Two papillomas, one of which was malignant, developed after application of the non-cancerous extract, five papillomas, one of which was malignant, followed the cancerous extract No extracts of European livers, however, gave rise to any tumours As in the former experiments, children's livers would have provided a better control, but these may not have been obtainable So far the data point to a cancer factor in livers whether from non-cancerous or cancerous subjects or to the development of one during handling in the laboratory Human liver extracts examined by Hieger[5] gave similar non specific results This work appears to have reached a stage where obscurities might be cleared up if performed wholly on animals The proportion of tumours likely to follow injection of liver extract from normal or non cancerous mice should offer no difficulty except the quantitative one Any increase in tumours attributable to the cancerous nature of their owners could also be found by pooling all livers over a period of time from cancer-bearing stock mice The influence of either extract on the incidence of spontaneous lung adenomas could be controlled better by using a strain in which this tumour was known to be low.

CONGESTIVE HEART FAILURE

According to Dr Samuel A Levine[6] the improvements in the last twenty years in the treatment of heart failure have come not so much from any notable new discoveries as from a more intelligent and effective use of old remedies This is true up to a point, but there have been advances which have changed our lines of treatment, for this period has seen not only the increasingly rational use of digitalis and the recognition of the limitations of oxygen therapy and venesection but also the introduction of the organic mercurial diuretics Moreover, as Levine says, we have come to realise the vitally important differentiation of peripheral from central circulatory failure and that to ply the unfortunate victim of lobar pneumonia complicated by peripheral circulatory failure with digitalis and diuretics is not only useless but often definitely harmful The significance of thyrotoxicosis in the ætiology of heart-failure, particularly with auricular fibrillation, has also been more generally recognised and Hay among others has pointed out that in patients with thyrotoxic heart failure the thyroid enlargement may not be detectable clinically, though this is no reason for recommending subtotal thyroidectomy in all cases of heart failure of doubtful origin Kinsey and White,[7] too, have clarified the ætiology by their finding that fever, however slight, in congestive heart-failure is evidence of some complicating condition, the commonest being pulmonary infarction, pulmonary infection (especially bronchopneumonia), active rheumatic infection, and coronary thrombosis

In the management of congestive heart failure we still rely on the triad of rest, digitalis and diuretics Of the value of complete rest there can be no doubt, though Levine reminds us that in some patients, particularly elderly ones or those with primary left ventricular failure, rest in bed may aggravate rather than alleviate the condition For this well recognised state of affairs in which the heart is embarrassed by the increased return of blood to its right side, the cardiac bed, the top third of which can be raised and the bottom third lowered, is preferable to the old-fashioned combination of a comfortable chair and a table on which to lean Digitalis is still our stand-by in all forms of congestive heart failure, whether with auricular fibrillation or normal rhythm,[8] and the main advances have been in the reliability of the various preparations of digitalis on the market, and in the recognition of the need for adequate dosage, though the massive dosage popularised in America by Eggleston[9] has not been widely accepted here Expensive proprietary preparations are no longer required in the ordinary case, and Evans[10] has demonstrated that the powdered leaf is the best and also the cheapest form of digitalis for maintaining equable digitalisation The work of Fraenkel and his colleagues[11] on the value of strophanthin has, for some reason, not received due attention in this country, despite Lewis's[12] teaching, there is something to be said for the intravenous administration of strophanthin in doses of gr 1/100 in the few cases where immediate control of the ventricular rate is required Quinidine sulphate by the intravenous route has also proved its value in cases of paroxysmal ventricular tachycardia when all other measures[9] have been tried and the heart is failing, and acetyl-β-methylcholine has established itself in the treatment of paroxysmal supraventricular tachycardia[13]

The question of which diuretic to use in congestive failure has now been definitely settled, the organic mercurial diuretics have proved superior to all others Indeed, in adequate dosage—2 c cm intravenously every third or fourth day—they have almost done away with the need for mechanical removal of œdema fluid, certainly Southey's tubes may be relegated to the museum, and there are few cases of hydrothorax which will not respond to these drugs In ambulant patients who have shown clinical evidence of cardiac œdema and received the appropriate treatment, they often prevent, or at least postpone, a recurrence Bleeding is now rarely needed

LITTLE's [2] request in Parliament for a Royal Commission, to which the Prime Minister replied in terms which indicated only too clearly the probable burying-place of the B M A commission's findings Meanwhile what can we outsiders do to help ? Just now there are many gatherings of doctors, young and old but especially young, which might find it a better exercise to devise their own plans for medicine or any of its branches than to find fault with the B M A 's, and we would gladly grant them space for such reasoned forecasts as the one printed on p 187 of this issue

Annotations

ERYTHEMA NUCHÆ

MANY of us have been asked by the mother of a new-born baby to explain the significance of a red staining of the skin in the occipital region or on the eyelids The inevitable maternal fear that the condition is a "birth-mark" is either expressed in the question or at any rate is the cause of the questioning The old hand will be able to give reassurances because he has often seen the condition, has observed that it certainly becomes no worse as the infant grows older, sometimes even disappearing from the facial region and being conveniently hidden in the occipital areas The inexperienced, on the other hand, may be doubtful about what looks at first sight like a large port-wine stain and for this reason some observations by F Ray Bettley [3] are worth noting Bettley uses the term erythema nuchæ but admits that the lesions bear some resemblance to a nævus and are probably only different in degree from a mild type of port wine stain He examined over 150 infants in the maternity department of Cardiff Royal Infirmary and found this variety of erythema in three quarters of them, the sexes being equally affected The commonest situation was the occiput (84%) where it was usually symmetrical and measured 1–2 in across, but the occiput was only involved alone in about 40%, other situations in order of frequency being eyelids, forehead posterior fontanelle, lip, retro auricular region, parietal region and vertex Various combinations were common and the lids only, for example, were involved in 8 cases The incidence of definite hæmangioma was much less, 7 cases including one with a minute spot, occurring in the group of infants examined Searching for a possible cause of the erythema Bettley tested the theory of pressure by studying the obstetric records in some detail Beyond showing a slightly increased incidence among the children of primiparæ, however, and some correlation between the type of presentation and the side of the eyelid involvement, where this was unilateral, the evidence was not convincing and the pressure theory is left unproven As regards prognosis Bettley examined an unselected series of 60 adults attending the skin department of the Cardiff Royal Infirmary, and found that half of the men and more than half of the women had some degree of erythema in the occipital region The eyelids and forehead were normal in every case In most instances the erythema was slight and its existence was unknown to the patients or their parents, but in 4 cases it was more definite It may be concluded from these observations that erythema nuchæ requires no treatment, that when affecting the facial regions it disappears spontaneously and in the occipital region usually tends to diminish in intensity Its ætiology is unknown, but the alarm it may cause in the new-born baby's relatives can justifiably be dissipated

VITAMIN C ON THE MARKET STALL

As the result of Miss Olliver's [1] work on the decrement of vitamin C in fruits and vegetables in the 24 hours after they are gathered it has been rashly assumed that the green vegetables exposed for sale in the East End of London three or four days after picking are almost completely devoid of vitamins This Miss Gweneth Chappell [2] has now shown to be entirely false, in a study of the vitamin C content of greengroceries on sale at cheap and more expensive markets It is true that in the majority of the 58 foods she investigated there is somewhat more vitamin C in those from an expensive market than in those from stalls, but in many cases—e g , the cabbage, tomato and radish—there is significantly less It was easy enough in 1939–40 to obtain a day's ration of 30 mg of ascorbic acid in a cheap market by the expenditure of a farthing (brussels sprouts, black currants, curly kale, lemons, oranges, spring greens, savoys, turnips and watercress) to three farthings (ripe banana, grape fruit, onion, parsley) "It appears," concludes Miss Chappell, "that avitaminosis occurring amongst those of limited means is due to an improper dietary, caused by poverty and ignorance, rather than to an insufficiency of ascorbic acid in the foods purchased on the open market" She confirms that fruits and vegetables bought in the open market have less ascorbic acid than freshly cut garden produce, and that the decrement is greatest in sprouts, potatoes and peas, while black currants, gooseberries and raspberries do not show so great a loss, and she calls attention to the importance to the health of the nation of encouraging allotment schemes Now that our main foreign sources of ascorbic acid have largely disappeared from the markets, this is even more important

THE SEARCH FOR CHEMICAL CARCINOGENS

EVER since cancer producing chemicals were made in a laboratory by Kennaway and Cook, efforts have been renewed to find these or similar substances under natural conditions within the body Kleinenberg, Neufach and Shabad [3] now claim that they have done so In a series of well controlled experiments on large numbers of mice they found a variety of tumours following the subcutaneous injection of extracts of human livers The livers were obtained from patients who had died with malignant disease elsewhere in the body In the control experiments they were derived from those who had died of other causes Details are given of the method of extraction, of injection and of the general and local reactions in the mice The number and nature of the tumours which occurred in stock mice at the same time was also recorded In the group injected with liver extract from cancer bearing subjects the incidence of tumours was 57 4% in mice which survived for eight months, of which 45 3% were lung adenomata , of those injected with liver extract from non cancerous subjects 24% bore tumours, of which 26% were lung adenomata , and among the stock mice surviving for eight months there were 10 3% bearing tumours, of which 8 48% were lung adenomata The rise in incidence of tumours in both the experimental series is impressive An equally striking feature is their great diversity Only six were seen at the injection site, and these were varied All the others were found at a distance in skin, mammæ, liver, thymus and maxillæ, and their histological characters were also different In respect of the diversity of type and origin of tumours the response to liver extract was thus unlike that which is known to follow injection of the synthetic chemical carcinogens with the exception of some azo

FUTURE OF CLINICAL PATHOLOGY

ITS PLACE IN A SOCIALISED MEDICAL SERVICE

By D Stark Murray, M B , B Sc Glasg
PATHOLOGIST TO THE ROYAL HOSPITAL, RICHMOND

CLINICAL pathology advanced with great rapidity as a result of the last world war and there are indications that it may receive another impetus from the present one No branch of pathology is static and those concerned with detection of disease and departures from normal are still in the stage of development which may lead to greater diagnostic accuracy The rapidity of that development will depend to some extent on the attitude of the profession as a whole not only to clinical pathology but to the prevention of disease

RELATION OF CLINICAL PATHOLOGY TO MEDICINE

The attitude of the medical profession to clinical pathology and the clinical pathologist cannot be said to have reached finality There are still those who regard the clinical laboratory as a place from which, under orders, results confirming the physician's diagnosis may be forthcoming There are, however, others who would agree with Goodhart[1] that "pathology is and must remain the rock on which the house of medicine is built" Goodhart realises that successful medicine is only possible when there is "coöperation between ward and laboratory, but the cooperation must be a real one between equal partners" Such a partnership will only be possible when the relation of clinical pathology to other fields of medicine has been defined and accepted At the moment the clinical pathologist may be described as one who is skilled in the technological procedures valuable in the diagnosis of disease or the control of treatment, and practised in the interpretation of these procedures He may perform tests which provide answers nearing that mathematical accuracy which earns name of science , and his interpretation of ascer-ned facts may need to be as delicate as that which the ysician brings to bear on the sounds he hears with his thoscope In this interpretation the clinical patholo-t must leave the laboratory and relate his findings the patient , and in so far as he realises that individual actions must be taken into consideration so will his operation with the physician or surgeon benefit the tient He will work to the best advantage, of course, those cases where he is given a free hand and can carry t his tests in the order and at the time most likely, in experience, to yield results

Goodhart fears that we "are breeding a race of patholo-sts who regard contact with human beings as a con-minating influence" Medical science needs every pe of worker, but the greatest need will always be for ose whom Zinsser[2] describes as "coordinators prepared bring the laboratory to the wards and the wards to the boratory" We shall make a serious mistake if we ink of clinical pathology as a service provided only in rge hospitals Dyke[3] appears to do so and is thereby d, in my opinion, into the error of expressing himself though clinical pathology meant hospital pathology ith a little "private practice" If clinical pathology essential to those working in fully equipped hospitals, ow much more necessary is it to general practitioners ho must deal with disease on their own initiative? uch has been written about improving the status and andard of general practitioners and it is undoubtedly ue that their association with the hospital service, as ggested in a recent pamphlet,[4] would produce the nprovement One factor in that process would be the pportunity to use that most valuable of tools, clinical athology That tool should, however, be available to every practitioner in his ordinary practice It would be of great value to the doctor, to the sick who desire rapid diagnosis, and to the community, which wants early detection of disease The clinical pathologist, too, has much to gain by association with the work of the disease-prevention agencies and with the general practitioner Pathologists who are only enraptured by the rare or intricate cases often complain that they are asked to do too many tests that produce only normal results Yet it is only by a sufficiently large background of these averages which we call normal that the finer reactions to disease may be gauged Such a background would be provided by work in the homes of the people and in clinics and surgeries, and the benefit to the community that would arise from new methods of detecting minor changes would be equalled by the advance in clinical pathology that this work would ensure

The association of the laboratory with the civil population would have further implications The clinical pathologist cannot work with the general practitioner and the disease-prevention services without being required to take part in epidemiological bacteriology There is, of course, much work to be done by experts in this subject and large-scale investigations are for the specialist , but the clinical pathologist is concerned with everything which affects the patients of the doctors with whom he works He must therefore be viewed as one part of the team which serves a community and not as a man who confines himself to a particular set of problems If he is well trained he will know when he requires the help of experts in one branch or another Closer relation with the bacteriologist engaged in whole-time study of infectious disease will benefit all laboratory workers The primary detection of diseases such as diphtheria and typhoid is rarely the work of the bacteriologist Diphtheria comes under the care of the general practitioner, typhoid is often admitted to a general hospital In both cases the pathologist has to make or confirm the diagnosis, and his laboratory must be conveniently situated. Where many laboratory examinations are needed it is obviously preferable that they should be carried out by one staff and interpreted by one expert The community served by a laboratory must therefore be of a size to require a laboratory large enough to carry out routine procedures at an economic cost, and small enough for the staff to be familiar with all the work passing through it This question of laboratory size introduces a different conception from that of Dyke although one would agree with him that all hospitals over a certain size must have a trained pathologist

In these circumstances the clinical pathologist becomes one of the most valuable liaison officers between the different parts of the medical services This is no theoretical suggestion but one which has worked out, in a variety of ways according to local conditions, in various parts of the country I have experience of an area in which it has worked for many years Now, under the Emergency Pathological Service (E P.S), the laboratory concerned does the clinical pathology for one large hospital, three cottage hospitals, and an isolation hospital, for the five boroughs which these hospitals serve, a large barracks and for over a hundred practitioners in these districts It follows that no case of meningococcal meningitis or typhoid, for example, occurs in the district without the laboratory staff knowing about it and being able to follow it up at every stage from the first visit by the G P to its removal to hospital and on to convalescence The laboratory is constantly consulted by practitioners, medical officers and hospital staffs about individual cases and about outbreaks of infections, and is often in a position to give information more rapidly than it could be obtained by any other method For the laboratory staff itself it is invaluable to be able to follow up every type of case, to discuss treatment—and in modern serological and chemotherapeutic methods the clinical pathologist plays an important rôle—and to correlate findings about different patients as they move from one medical sphere to another Patients do not always remain under the care of one doctor, but though, in the area under discussion, patients may change their personal or even hospital doctor they do not change their pathologist; and this has valuable and occasionally amusing results

except in a few cases of left ventricular failure, and Ebert and Stead's[13] observation that as much blood is removed from the general circulation by a venous tourniquet on the limbs as by the usual phlebotomy should tend to diminish still further the need for this traditional line of therapy. The introduction of the B.L.B. mask, whereby oxygen at concentrations up to 100% can be given for long periods, has called for a *revision of opinion on oxygen therapy in heart-failure, particularly in view of the successful results obtained in* coronary thrombosis. Finally, the problem of the best diet for patients with congestive failure has been at least partially solved by insisting on as little restriction as possible. The Karell diet has received a new lease of life. In view of the hypo-proteinæmia present in certain cases of congestive heart failure the patient's diet should contain as large a proportion of protein as his digestive tract can cope with; whether the Karell diet of 800 c.cm. of milk daily meets these requirements is doubtful. There is now general agreement that salts and fluids should be restricted, though not to the pitch of causing discomfort to the patient.

RESPIRATION IN THE NEWBORN

Bauer,[1] of Detroit, has made a useful mechanical study of some of the questions about respiration in the newborn which remain unsolved. He felt that it was desirable to have a more definite picture of the relative functions of the diaphragm and chest wall in normal respiration, particularly because such understanding will help in the safe employment of any mechanical means to initiate or improve respiration in the newborn baby. The apparatus Bauer used consisted of two cloth-enclosed rubber tubes ("cigarette drains") similar to the cuff of a sphygmomanometer, one encircling the abdomen just above the umbilicus and the other the chest at the nipple line. Each was attached to a recording tambour by small rubber tubing. A third pen recorded time in seconds. After the tubes had been applied, the baby was placed in his crib, covered and allowed to go to sleep. The tubes were then gently inflated—the degree of pressure did not appear to affect the results—and the recording started. Nineteen healthy infants were studied, ranging from 1 to 10 days in age and 6 to 9 lb. in weight. Most of the tracings lasted over a period of 5–10 minutes and fortunately in most instances the babies remained asleep, some soundly, some lightly. The rates of breathing were higher and much more varied than has hitherto been described. The slowest average rate was 28 per min. in a completely quiet infant and the highest 120 in an infant who was crying, but a maximum rate of this degree was also found in a quiet infant and in another with hiccups. The average for all the observations was about 60 per min. It was found that the amplitude of the abdominal movement was from two to five times as great as that of the chest. At least two types of related movement were found in all the babies. In one the chest expanded slightly with expansion of the abdomen and in the other there was a retraction of the chest just before full expansion of the abdomen. Bauer explains these observations on the basis that when breathing is rapid and shallow the chest expands with the abdomen—i.e., with diaphragmatic descent—but when breathing is slower and deeper the more forceful pull of the diaphragm produces retraction of the relatively weak, elastic chest wall. These observations throw some light on the ætiology of atelectasis, at any rate in a negative way. Weakness of the chest wall has been considered a possible factor in non-expansion of the lungs, but Bauer found such weakness in some degree in all these healthy babies, suggesting that cohesion of moist alveolar walls and bronchial obstruction are more likely factors. Another point which he makes is that there should be no mechanical interference with respiratory movement, unless it has never started or has stopped completely, because it is unlikely that any apparatus for artificial respiration could be regulated to follow the great variations in rate and type which are present in the newborn. He suggests that some means of holding the chest in a position of full expansion for short intervals might help by eliminating the retraction caused by the pull of the diaphragm in laboured breathing. Bauer's records show that crying causes the greatest degree of expansion of the chest and abdomen, and, intelligently used so as not to cause trauma or make things worse for a severely asphyxiated baby, the production of a "lusty cry" still remains justifiably popular as a means of starting off or deepening early respiratory effort.

IMMUNISATION AGAINST SCARLET FEVER BY MOUTH

VARIOUS reasons can be given why immunisation against scarlet fever is not at present a practicable—or even necessary—procedure. The repeated injections of toxin with a fair proportion of both local and constitutional reactions, the mildness of scarlet fever, and the fact that immunisation against the erythrogenic toxin does not protect the individual to any degree against the streptococcus itself have together prevented a wide usage of this prophylactic measure. Yet, immunisation against scarlet fever may from an administrative viewpoint be desirable in certain circumstances—e.g., among nurses in fever hospitals, children in residential schools, and in institutions where an epidemic of the disease has lately occurred. To overcome the difficulties associated with the ordinary method of shallow hypodermic injection of the toxin in graduated doses over a period of five to six weeks, the Dicks[1] have been exploring the possibilities of immunisation by the mouth. Obviously the liquid toxin could not easily be distributed in large quantities for oral administration, so they prepared a purified toxin in powder form, which, given either in saccharose or in syrup, caused a considerable amount of nausea and vomiting, as might be expected in view of the known affinity of scarlatinal toxin for the gastric mucosa. Enteric-coated tablets were therefore prepared and used with success, although some failures resulted either from the coating being dissolved in the stomach, causing gastric upset, or from its being undissolved because of rapid passage through the gut. The optimum dosage is 75 million skin-test doses given once daily after a meal for three weeks in gradually increasing amounts from 100,000 S.T.D. to 6–10 million S.T.D. on each of the last few days. Of 102 people who received amounts of toxin ranging from 47 to 91 million S.T.D. over a period of two to three weeks, 94.7% were immune on retest. In 4 of these cases, transient scarlatinal rashes appeared, usually after the 4 million dose; 2 people vomited once. The advantages of the oral route seem to be in the shorter period of immunisation and the avoidance of local reactions; it will be particularly valuable for people who are allergic to foreign protein.

SIR JOHN MCFADYEAN, formerly principal of the Royal Veterinary College, died on Feb. 1 at Hindhead in his 88th year.

Prof. A. H. BURGESS will deliver the Hunterian Oration before the Royal College of Surgeons of England on Feb. 13 at 2.30 P.M. His subject will be Charles White of Manchester and he will speak at 1, Wimpole Street, W.1.

age in the city, of whom about 13,000 would be artificially protected In 1939 there were 104 notifications of diphtheria, of which 22 were in children who had been inoculated In 4 of these the diagnosis was not confirmed and in 4 others inoculation had been performed elsewhere than by the public-health department Of the total of 13 258 children known to have been protected 128 have been notified for diphtheria since 1927, the diagnosis being confirmed in 67 and rejected in 61 The incidence of diphtheria amongst protected children under thirteen was therefore 1 in 200, which is less than a tenth of the expected incidence This confirms the claim made for immunisation that it reduces the incidence by nine-tenths and abolishes fatality All available information, which is now immense, justifies this claim

NEWPORT, MON

Dr H W Catto s report for Newport is fully comprehensive As in other parts of Britain, the health of this county borough in 1939 was a record for goodness, but there was one unsatisfactory feature in the maternal mortality-rate of 6 7 per 1000 births live and still In the two preceding years the rates had been 1 27 and 3 18 and in former years the rates had not been high Two of the ten maternal deaths were due to sepsis, an average number for the town, but both followed miscarriage We are not told the duration of the pregnancies —whether the products were abortions or stillbirths— but the occurrence demonstrates the confusion in estimating the maternal mortalities of English districts The Puerperal Pyrexia Order, now incorporated in the Public Health Act of 1936, leaves it uncertain whether pyrexias following abortion are, or are not, notifiable and consequently whether deaths accruing from it should, or should not, be reckoned in casting the puerperal mortality The word used in the law is not abortion but miscarriage, which is not defined and in practice is used loosely, by some as synonymous with abortion, by others with premature delivery, by others to cover both

In 1832 Newport covered 938 acres and had a population of 7062, in 1936 its area had grown by encroachment to 7873 acres and its population, mainly by natural increase, to 97,500 Between 1904 and 1939 its birth-rate fell from 32 48 to 15 46 and its death-rate from 15 63 to 12 87, the present tendency being for the former to fall still further and the latter to rise slightly The infantile mortality varied very little from 1877 (167 2) to 1904 (153 9) but was halved by 1934 and in 1939 scored the low level of 53 6 This reduction to a third of what it was 30 years ago goes but a very slight way to counteract the fall in the birth-rate, and the fall in the general death-rate, which is comparatively slight and, now being reversed, has not done much more to maintain the population level, for though it is still growing in numbers it is ageing rapidly The stillbirth-rate in Newport was high, 46 3 per 1000 total births, or 0 76 per 1000 population, against the average of 0 59 for the 126 great towns Dr Catto says that the results of the compulsory registration of stillbirths reveal that the records for the years before registration are fairly reliable In Newport the stillbirth-rate, after falling for several years, is again rising It is curious how this rate varies from year to year and from place to place The rate should fall steadily with the improvement of midwifery, but it has not done so with the regularity we expected In 1900 the percentage of total deaths occurring in persons under 5 years was 45 2 and in those over 65 years 15 6 In 1939 the former had shrunk to 8 16 and the latter risen to 51 3 This record, though not exceptional, is a remarkable testimony to the advances made in the present century

GILLINGHAM, KENT

In the borough of Gillingham, of which Dr W A Muir is M O H, the infant mortality in 1939 was 32 and the stillbirth-rate 29 There were 34 illegitimate pregnancies running to viability of which three ended in stillbirth and 31 in livebirths with no infantile mortality These numbers are too small to have much significance, but the record is interesting in showing the combination of a low infantile mortality with a low stillbirth-rate in legitimate and a low infantile mortality with a high stillbirth-rate in illegitimates These two combinations were frequent in 1939 Neonatal death is in the main of similar causation as prenatal death and therefore the rise and fall of the one should vary inversely with the other, but death during delivery is preventable by skilled midwifery, so improvement in midwifery does to some extent reduce the total of the two divisions Good midwifery may ensure the live birth of an infant incapable of survival—such as an anencephalic—which is of no value from the infant's point of view, but is of considerable value to the mother, for it means a less severe or prolonged labour The decrease in the postnatal mortality of illegitimates is a recent gain of great value but the prenatal mortality of illegitimates is still comparatively high The explanation is that owing to the compulsory notification of births the born infant can be brought under supervision, whereas pregnancy not being notifiable unmarried mothers usually escape supervision Out of a total of 32 infant deaths, 22 were due to congenital debility, prematurity and malformations

In the twelve years 1928–39 the attack-rate of diphtheria varied from 0 13 in 1932 to 1 1 in 1938, the average being 1 26 In the ten preceding years it was 1 24 Though the annual incidence of diphtheria fluctuates widely, the average has remained unaltered for a great many years, not only in Gillingham but in most districts of Britain In America the incidence has been falling since Osler's time, and since the introduction of inoculation it has sunk extremely rapidly We can expect a similar result from inoculation in Britain

LEAMINGTON SPA

Dr E R Gilmore, of the borough of Royal Leamington Spa, records a zymotic death-rate of nil, an infantile mortality of 31 3, a tuberculosis mortality of 0 54 per 1000 population and the average age of death as 65 years Of 411 births, 16 were illegitimate, 4 of these died, giving an infantile mortality of 250 Amongst the legitimate infants the mortality was 21 6, astonishingly low for a town of 30,000 inhabitants, the stillbirth-rate was 19 5 per 1000 total births, which is also remarkably low People certainly live long in Leamington, for of 412 who passed away in 1939 only 152 failed to reach 65 and the same number scored 75 or more The birth-rate in 1939 was 13 4, the highest since 1930 The average birth-rate for the past thirty years was 11 8 and the average death-rate for the same period 14 8 also The average infantile-mortality rate for the period was 60 2 It did not fall much before 1932, but in 1934 it was only 8 9, which surely must be a record However, the average of the three years 1933–35 was 33 4, so the record was "accidental"

Infectious Disease in England and Wales

WEEK ENDED JAN 11

Notifications —The following cases of infectious disease were notified during the week smallpox 0, scarlet fever, 1164, whooping-cough 2761, diphtheria, 1233, enteric fever, 30, measles (excluding rubella), 15,413, pneumonia (primary or influenzal), 1465, puerperal pyrexia, 119, cerebrospinal fever, 266, poliomyelitis, 5, polio-encephalitis, 1, encephalitis lethargica, 2, dysentery, 93, ophthalmia neonatorum, 73 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Jan 17 was 2321 including scarlet fever 325 diphtheria, 343 measles 902, whooping cough 140 enteritis 23 chicken pox, 216 erysipelas, 50, mumps 25 poliomyelitis 2 dysentery 53 cerebrospinal fever 46, puerperal sepsis 6 enteric fevers 7 german measles, 4 other diseases (non infectious) 91 not yet diagnosed 88

Deaths —In 126 great towns there was no death from smallpox or enteric fever, 1 (0) from scarlet fever, 22 (2) from whooping-cough, 23 (1) from measles, 43 (3) from diphtheria, 36 (4) from diarrhœa and enteritis under 2 years, and 69 (9) from influenza The figures in parentheses are those for London itself

There were 6 deaths from diphtheria in Liverpool Birmingham reported 7 fatal cases of whooping cough Greater London had 1 fatal case of enteric fever

The number of stillbirths notified during the week was 217 (corresponding to a rate of 38 per thousand total births), including 13 in London

ECONOMIC FACTORS

It has long been recognised that expansion of laboratories is made much easier when they have some method of "boosting" their incomes Laboratories are not an expensive item in a hospital budget, and even at such low rates as that now charged in the E P S may show a profit on paper, yet hospital committees still appear to expect laboratories to find some way of paying their cost So long as a fee system remains, the best method is that of associating the laboratory with public-health authorities and general practitioners Under such conditions the pathologist should be employed on a basis which recognises that he must be free to move from hospital to hospital and to visit patients in their homes This touches the wider problem of organisation of the medical services as a whole, for a laboratory service cannot be perfectly organised if the rest of medicine remains on its present anachronistic basis It is true that the present E P S attempts to fit itself to existing conditions, but both in the circular which at present controls it and in the remarks of the ex-Minister of Health to a deputation of the Socialist Medical Association, it is conceded that such a service can only be provided as a fully socialised service—that is to say, it is available to every member of the community, whether in hospital or at home, and the provision of the necessary assistance to doctors and patients comes before the question of fees The scheme also accepts, by its relation to the sector arrangements, the principles of regional organisation and of inclusion of all laboratories in the area

THE UNIT PLAN

The supreme importance of clinical pathology can only be demonstrated and put into operation as a service when the form of the medical service of the future has been decided That it must be a fully socialised service will be universally accepted when the profession and the public recognise what such a service would provide In a fully socialised medical service four cardinal principles would be recognised completeness, universality, unification and regionalism These principles would give medicine its first opportunity to reach full scientific stature, enabling the profession to concentrate on health-preservation and disease-prevention, rather than on treatment and palliation, they would provide a service sufficiently flexible to meet all demands on it, even those of major epidemics, and at the same time would give to doctors conditions of work that have even yet not been clearly visualised

Regionalism must not be confused with that other conception, regionalisation, now the basis of the E M S, of the work of the Nuffield Trust and probably of future local government Regionalisation simply recognises that a more efficient and economical arrangement of services is possible when the country is divided into regions, mostly larger than the traditional boundaries of local authorities It is inevitable that the control of medical services will follow similar boundaries to those laid down for other services, so that while the Ministry of Health may lay down the national policy for medicine there will be an opportunity for adjustments to local conditions This will not safeguard true democratic control (true in the sense that each individual will have a chance to influence those services which affect his well-being) nor will it provide a medical service in which the patient can feel confidence unless at the same time regionalism is adopted Regionalism cannot be fully explained without a consideration of the probable basis of a socialised medical service, but it depends on the same conception as that put forward above for a pathology service—the conception of a unit of population of a size convenient for doctors and patients alike In the Walton plan[5] a unit of 100,000 has been taken for purposes of illustration, but a close examination of population distribution, transport facilities and social habits is needed before the best size of unit can be decided in each locality Flexibility is essential, and the opinion of local doctors and patients would help in establishing a series of regional units sufficiently large to be efficient and small enough to satisfy all those demands for personal attention and knowledge which some fear a socialised service might not meet

In each region there should be a full domiciliary, hospital and specialist service, and all the ancillary services a doctor needs must be available both in the homes of the sick and in clinics provided for the maintenance of health There are a number of services—research, educational and highly specialised—which would serve more than one regional unit but be just as *easily accessible to every patient and doctor* There is *of course no double standard of treatment in those* diseases for which a specific remedy has been found, and there is no valid reason why a double standard of attention or treatment should continue in any part of medicine There should be only doctors and patients and both should have every help that science and organisation can give If the profession is to be welded into one service with interchangeable personnel, with rapid dissemination of new methods and ideas, and with a basic standard below which no part may be allowed to fall, it is essential that there should be unification The service postulates which would be universal, unified under one authority and so closely related to the needs of the individual through regionalised control that there would never be any danger of it becoming stereotyped *or bureaucratic It would react to the demands of those* mainly concerned, the doctors and the sick The problem, as Zinsser says, "is to find a solution which shall meet the requirements of effective scientific care of all those who require it, and at the same time that sense of personal responsibility, compassion, and judgment without which the physician becomes a mere technician" This problem can be solved for clinical pathology by the type of service described

---

[5] *Medicine Today and Tomorrow* March, 1939

Public Health

From the Annual Reports

HAMPSTEAD

From Dr H Leslie Oldershaw's report of the metropolitan borough of Hampstead we learn that in 1939 in a population of 90,000 there were no deaths from measles and only one from whooping-cough, and in 980 births only one maternal death There were 39 deaths from pulmonary tuberculosis, 38 from pneumonia and 39 from violence other than suicide For some years these three causes of death have been competing for first place in the death table after cancer and the senile group of diseases Violence is winning Though in theory fatal violence is the most preventable of all means of death, in practice it is not preventable, for with the exception of suicide, homicide and execution, all violent deaths are accidental, that is, due to failure of prevention through human error They do, however, admit of some limitation by medical means, for accident proneness is an entity sometimes due to physical or psychological states which can be diagnosed

LEYTON

In his report for Leyton Dr Andrew W Forrest gives an account of the establishments for massage and special treatment In April, 1934, Leyton corporation took over the powers and duties of the Essex County Council Act of 1933 in regard to licensing these establishments and made by-laws for the conduct of the business These by-laws are concerned with the respectable management of the establishments, but, as Dr Forrest emphasises, do not prescribe the technical qualifications of the persons administering treatment, and he recommends that in future licences be granted only to persons possessing technical qualifications recognised and approved by the Board of Registration of Medical Auxiliaries We presume the Essex County Council Act conveys power to make the appropriate by-laws

PLYMOUTH

Immunisation against diphtheria has been practised in Plymouth since 1927 In the last five years the numbers of children who completed the course of injections were 2118, 1766, 1535, 1137, and 1183 The number of births in the city last year were 3446 There would be about 42,000 children under thirteen years of orners are sometimes no longer available for there was much damage below ground and water is leaking into he station at many points but repair work goes on night nd day, and there was hardly any interruption of the unning of the trains

* * *

A friend of mine is in charge of a large camp for prisoners He tells me that one of the most remarkable hings about the feeding of the men is the small amount of swill the Germans make—they waste about a third of what our men do and they render down every bit of fat available Mr J B Priestley has told us to look forward to communal restaurants as social centres and we may imagine other advantages in them too Another friend of mine a well-known caterer tells me that the by-products alone will make them worth while Breadrumbs, potato peelings and cheese rind are all valuable by-products but meat he says, yields more useful things than any other article of food, and they can be extracted rom it to best advantage in a communal kitchen If 5000 people are allowed 4 oz of beef per head and carry it home to cook a joint of 1 lb will serve four people and a joint of 6 lb twenty-four, but housewives will agree, he tells me that from the 1 lb joint nothing will be left, and from the 6 lb joint there might be enough bones to make soup for five of the family and enough dripping for four of them to have bread and dripping for tea And what would happen to the bones of the carcass? Did 10% of them—for they are valuable—find their way to the contractor? And did the butcher boil the large bones before he sent them to the contractor? He should have done for the contractor finds them just as useful to him cooked as raw, and the remains of meat upon them would have made rich stock Suppose the same amount of meat—1250 lb—had been issued to 5000 communal eeders There would be roughly, I was astonished to earn three forequarters and four hindquarters of meat in this allowance After giving everyone roast beef for their midday meal from the bones of the seven quarter carcasses, it will be possible to give 3000 people a really good soup in the evening From the skimmings from the top of the stock-pots when the bones are boiling to make this soup, it will be easy to extract enough fat to give everyone half a slice of fried bread the following morning Fat taken from the carcasses before the joints were cut up and put in the roasting ovens will yield enough dripping to give everyone enough for a good spread on bread for tea And 95% of the bones will have gone to the contractor The dripping made from the fat cut from a carcass before it has been boiled or roasted is called in the Army first-class fat and that from the skimmings of bones being boiled for soup, second-class fat My catering friend does not approve of these descriptions because the fat or dripping called second-class is far more palatable than that called first-class The balance in favour of communal feeding as far as meat goes—and, as I now realise, it goes a long, long way—is tremendous and he assures me that other foods are saved in the same proportions Yes communal feeding should be here for the duration

* * *

If at times I get discouraged I go and talk either to workmen or antique dealers It sounds an odd combination but the reasons for my choice will appear later A few weeks ago I was asking a lad of seventeen about the hours and conditions of his work He forges parts of aeroplane engines for 12 hours at a stretch and works by day one week and by night the next "Do you feel very tired after your 12-hour shift?" I asked "Yes, just a bit," he replied "Only a bit? Do you really feel that you could go on after 12 hours of it?" "Of course, sir after all we've got to win the war haven't we?" I could not resist patting his sturdy shoulder with a "that's the stuff to give 'em" And all the lads I spoke to had the same spirit Not being a Southron I feel all the more entitled to praise these gallant English boys There is nothing decadent about them, nor are they dull clods or blind mouths, as Milton has it They are highly intelligent and are made of the same stuff as the Elizabethan adventurers In some ways I imagine that they are even better than the Elizabethans, because there was probably more romance in sailing the Spanish main than in working in a steel factory—though the factory has a grimly romantic atmosphere all its own

I daresay that others besides myself have noticed that antique dealers as a class are charming people They are probably drawn to antiques because they are sensitive to the beauty of line and mass and colour of the things made by craftsmen, and most of them are passionately in love with their wares Sensitiveness to beauty does not necessarily go with charm of manner and friendliness, but the fact remains that in antique dealers it usually does A grocer would not as a rule welcome anybody into his shop to discuss the æsthetic qualities of his rows of tinned conserves, and it would be a brave customer who would do so and then leave the shop without a sample of one of the 57 varieties But I often go into an antique dealer s shop and see and discuss things worth looking at and leave without buying one True I have not always gone into these honey pots and escaped without things sticking to me, and I do not regret the adhesion of such things as an oil painting by Etty, a water-colour by C J Fox, a dainty imperial yellow porcelain bowl of the K'ang Hsi period or some old English wine glasses Some things the dealers will not let go They like them too much One of my antique dealer friends has a beautiful old mirror in his sitting-room and nothing will induce him to part with it Several times have I sat in one of his Chippendale chairs and admired it silently and vocally But the other day when I was making a nuisance of myself again about it he said, "I don't think you have any specimens of Chelsea china in your collection Here is a lovely little piece which I've kept for you You'll notice the smoothness and peculiar excellence of the glaze and how delicately the exotic bird has been painted" When I asked about the price he indicated rather shyly that it was a gift His delicate gesture delighted me and I felt as if I had a collection of Chelsea china as magnificent and complete as that of Dr Bellamy Gardner Incidentally I forgot all about the mirror and the exigencies of the war

* * *

The effect of disease supervening on existing disease must have been noted and aroused curiosity from time immemorial It is a subject historically best suited to the patient, thorough, critical compiler, such as one finds among Germans It can hardly have escaped the attention of some historically minded investigator, but if there is some work on it I have not seen it There is also the problem of the mode of action of one disease on another which could only have been investigated in recent times, involving as it does immunological and chemical research It is as worthy of a thesis as a good many subjects and would require more historical research than individual experience on the part of a candidate The experience, I think, lies locked up, with much else of interest, mainly in the memories of general practitioners Herpes on the lips and elsewhere in pneumonia is said, according to Fagge's "Medicine" (1888), to occur in from two-fifths to one-half of all cases, and he remarks that it is very strange that it is far more common in cases that do well than in those that end fatally He adds that this has long been a traditional opinion, and that it seems to have been established by the observations of Geissler (1861), who found that of 421 cases the mortality amongst those with no herpes was 29 3%, compared with 9 3% in those who had it Naegeli (*Munch med Wschr* 1936 83, 339) also speaks of the belief of experienced practitioners about the favourable influence of herpes simplex on other diseases, especially pneumonia, and confirms Fagge's quotation concerning the mortality-rate Why this influence? A further curious statement that I have seen is that the success of fever therapy in neuro-lues is most frequent and most pronounced in herpetics, especially in patients in whom a considerable eruption appears during the cure In some cases neuro-lues was favourably influenced by herpes-inoculation and subsequent activation with fever when a previous fever-cure had been ineffective This statement should be verified especially when diathermy or short-wave therapy is used

A very uncommon instance of the action of malady upon malady is reported from Sofia (cited in *Munch med Wschr* for Oct 21, 1938) A patient who had had diabetes for nine years developed severe diarrhœa, and was found to have atrophic cirrhosis of the liver Clinical recovery from the diabetes, or at least marked

In England Now

A Running Commentary by Peripatetic Correspondents

YESTERDAY I went to the Abbey for the memorial service to B-P, not an uncheerful occasion No-one in our time has given as much happiness and health as this, lovable boy-man, for not only has he inspired all those vast numbers who have been or are scouts or guides, but multitudes beyond, the week-end campers, that host of lads and lasses in shorts who bike or hike along country roads all over the world, a noble army of those who seek health in service Whatever form of immortality awaits us lesser folk, whether it be merely that we are transmuted to the wood and leaf of the churchyard elms, or flung to the four winds in gaseous form from the necropolis chimney, or sprout wings, or play on golden harps, this is certain, that for generations to come, whenever youngsters gather round a camp-fire, whenever the call of spring and adventure takes them into the wilds, whenever the joys of service summon them, B-P will be with them, sharing in their zest

After half a lifetime spent in the laboratory in unusually complete detachment from clinical medicine, I am finding a "war-emergency" return to the bedside absorbing Stout Cortez was not as stirred as I when I recently watched the meningococci in a daily smear become sparse even unto extinction under attack by sulphapyridine while the patient miraculously recovered, or a pernicious anæmia, thirty years ago to be labelled doomed, now burgeoning reticulocytes after a few injections of liver extract Rip Van Winkle could not have had the thrill of returning to anæsthesia, and, instead of half-narcotising himself daily with a too generous ether or chloroform fog, toying with the admirably efficient and almost foolproof gadgets of a late-pattern MacKesson And what a boon are premedication or anæsthesia with the barbiturates, and chemotherapy in pneumonia, and to help while a pulseless dying bombtorn victim is being plucked back by the wizardry of plasma transfusion, or a marble-white hæmatemesis grows rosy pink, is an experience to have lived for But alas I see that patients still die from ileus and exhaustion in the time-honoured manner General surgery does not seem to have moved much, and am I pernickety in blinking when the physician still visits his patient in uncovered outdoor garments and sans mask? As for minor horrors, my recent boil in a hardly respectable locus still bred its family of baby boils in the authentic tradition, despite the wheedling of mag sulph paste

* * *

Near one of the City's most famous landmarks may be heard the sound of picks and shovels, the rattle of pneumatic drills and the hissing of oxy-acetylene burners cutting through twisted girders and battered steel plates A vast crater teems with Pioneers breaking up masses of concrete, which are hauled up by big cranes It was the custom of the shelterers at this underground station to deposit their bundles down on the platforms and in the deep corridors, and then to come up to the booking-hall, just below street-level, where they found a well-lighted balcony with shops all round This was their Brighton pier, and for an hour or two before retiring for the night they were in the habit of promenading round, leaning over the railings, watching the escalators (on which children used to play) and gossiping with their friends It was Saturday evening, and the Shelterers' Parade was in full swing It is true that the sirens had sounded, but that was a long while ago, and no bombs had been dropped anywhere within earshot Not even a gun had been fired for about twenty minutes A policeman on point-duty overhead must have been almost the first to realise that danger had suddenly become imminent he heard the familiar sound "as of a rushing mighty wind" and he ran for his life to the nearest cover He was only just in time, next moment the city was shaken by a deep roar—a large bomb had fallen into the booking-hall and blown the roof off Concrete was hurled into the air, the blast travelled down the wide escalator shaft and through the open doorways, sweeping all before it, throwing people off their feet—many fell on to the line, of whom two, a soldier and a policeman, were thrown in front of a train which was just entering the station. Help for the victims was not long in arriving A mobile unit from the City corporation was soon on the scene, and even before this, a few yards from the crater, a dressing-station was set up in a surface-shelter in which two nurses attended to people who had been caught in the street A man lay on his back in the roadway, crying softly to himself, "Oh, my belly! Oh, my belly!" He had a ragged tear across the upper abdomen, his clothes were torn half off and his face so blackened with road dirt that he looked like a negro It was the work of but a moment to apply a sterile triangular bandage to the whole abdomen, pull his tattered shirt and waistcoat down over it and adjust his wide leather belt to hold the dressing in place A Tubunic ampoule of Omnopon was injected into the abdominal wall—both his arms were as black as his face Already a stretcher-party had arrived, and he was taken off to hospital Against the wall of a near-by building the police had propped up a row of casualties—a fractured forearm, a girl with a gash down the side of the face, a man with the top of his head knocked in (no pulse, blood-stained froth on his lips, quick, jerky inspiration followed by slow, bubbling expiration, probably due to hæmorrhage into the lungs—a common effect of exposure to blast at short range) As soon as these cases had been dressed we turned to explore the booking-hall and its approaches

Walking warily—for the street was littered with debris, and wide cracks had appeared in the paving manhole covers were missing, and the asphalt hung perilously over the edge of the crater—we entered one of the stairways leading down to the station About ten people were lying on the stairs, one had all his clothes torn off, another had a leg missing, severed at the knee, all were black with grime and every one was dead Halfway along the corridor our torches showed someone moving his arms, it was difficult to reach him, for the passage was almost choked with masses of concrete and twisted steelwork Also, there was a strong odour of coal-gas, a moment later this caught fire, but was soon extinguished He was trapped by his legs under a huge slab of reinforced concrete but already the rescue party was getting to work with jacks and levers, he was given an injection of omnopon (tubunic, of course—it was no place to try to fill a syringe) It took an hour to get him out, in the meantime he was made as comfortable as possible, with his head pillowed on the legs of a dead man just in front of him A woman's handbag lay on the floor, we peered into every dark crevice under the debris to find the owner, but there was no sign of her Either she or the handbag might have been blown a long way We went down by the emergency stairs to find that a large number of people had been injured below ground When a bomb explodes in such a confined space as this distance is of less importance than the width of the passages, and they happened to be exceptionally wide in this station The first necessity was a bucket of water and a large swab, even here the wounded were covered from head to foot with dirt It was impossible to do more than a hasty toilet, then apply those handy "mine dressings," each in a sealed paper covering, and with an adequate length of bandage attached, there are three sizes, and a small haversack will hold half a dozen small, a dozen medium and half a dozen large These, with a dozen sterile triangular bandages, also in sealed paper envelopes, a soft rubber tourniquet and three boxes of tubunics, provided all the outfit required for attending to some thirty or so of the casualties The highest praise is due to the station staff, who brought water, stretchers and tea to the improvised dressing station and operated a lift to the waiting ambulances In just an hour and a quarter the last of the injured was on his way to hospital But there was one case more, twenty hours later they found the booking-clerk, still alive, but terribly injured, he had been trapped in a corner of the entrance hall Hammers are swinging, the cranes whistle and clang, Pioneers sweat and tug at the chunks of concrete and tangled steelwork, already the site has been largely cleared and spanned by a temporary bridge for city traffic must pass, and under and around the bridge the engineers will set to work to rebuild the upper part of the station Tonight the shelterers are huddled along the platforms and deep corridors, there is no more Brighton pier for them Even their accustomed minutes with a solution of 3% anæsthesin in olive oil beforehand It was the use of this method which made me suggest in 1933 that there was another factor in hæmorrhage besides the factor of coagulation of the blood, something akin to a " turning off of the tap " as it were Hæmorrhage in a good many cases is not due to poor coagulation, but rather to the fact that the ends of the severed blood-vessels fail to close, and it is this factor which is usually present in dental operations

Sutton Coldfield, Warwick E VAUGHAN TOMEY

B M A MEDICAL PLANNING COMMISSION

SIR,—We have read with interest and appreciation your leading article of Jan 11 and the letter of Sir Ernest Graham-Little in the following issue It is a matter of regret and anxiety to many members of the profession that the British Medical Association, which is in reality a club of which membership is still voluntary, should be so widely regarded as representative of the whole profession Now that this body, which through its war committee was largely responsible for our present emergency service has set up a further committee to advise on post-war organisation it seems desirable to emphasise this point Even if the recommendations of this commission should prove more acceptable than ose of its predecessor they should in no way be regarded the considered wishes of the whole profession nor put to force without further consultation As junior embers of the profession we would especially support our criticism that the opinion of members of less than n years standing is not represented on the commission We feel that the future might fairly seem to be a major interest for us

ALASTAIR HUNTER,
KENNETH M A PERRY
London Hospital E 1 J MICHAEL VAIZEY

SIR,—A number of your correspondents have thought t—and rightly so—to criticise the constitution of the ommission on the grounds that the more junior members f the profession are not adequately represented This neglect of the younger medical man's point of view is ar-reaching and worthy of detailed consideration Until a few years ago medicine was even more predominantly in the hands of older men than it is today, when many of our most brilliant workers are men qualified in the last ten years , and the general public is becoming reconciled to the idea of a beardless doctor whose name has been on the Medical Register for a comparatively short time This has been one of the changes brought by the last war, but what greater changes may now be possible in a world which regards with equanimity changes and upheavals occurring almost overnight ? This relative ascendancy of the young man has come in great measure from outside the profession, and many of his present-day advantages have been accorded him with comparatively little effort on his part This may account for what seems to be his lack of interest in modern trends and tendencies At the beginning of the war a large number of hospital residents like myself were offered contracts by the Ministry of Health at salaries beyond our wildest dreams , but when these were peremptorily cancelled by a stroke of the ministerial pen, many of those affected had scarcely a word to say about it, and the ultimate restoration of the original terms was due to their good fortune and the good sense of the ministry, and not to any vigorous protestations from the doctors themselves At the same time, most of us had offered our services to the armed forces, but we remained subject to the rulings of local war committees, many of them composed of retired men who had little but local politics to occupy their declining years, and upon which we had no representation For example, of a committee of six in my own part of the country only one knew me personally , and I have often wished that they had judged me unsuitable for work in the Forces, for I would then have had an opportunity to explain some of the shortcomings of the E M S Surely it is evident that though the young postgraduate has been hardly used and looks like being in the rear rank again, it is in some measure his own fault and is due to his lack of interest and inertia ? Young men in medicine, as in every other walk of life, must fight their own battles Fourteen months as a " civilian in uniform " has shown me that young men in other callings have thought a great deal about the post-war period and are resolved not to allow their opportunities to slip by or be taken from them as they were from their prototypes after the last war Young men in medicine today work hard as hard as their fathers before them, but they tend to lose the broad view which we need so much today , and this arises partly from the ignorance of their elders and partly from their own sloth This war is primarily one of opposing sections of the youth of the world, so let us be afforded an opportunity to add our ideas and counsels to those of our elders so that we in due time may accept more of the responsibility which is at present theirs alone

Hammersmith, W 6 E N OWEN

DYSPEPTICS IN THE ARMY

SIR,—Professor Hartfall in his letter of Jan 25 criticises the findings which we put forward in our " Interim Report on Dyspepsia in the Army " (*Brit med J* 1940, 2 819) We must point out that he is under several misapprehensions First, the field work of this investigation was carried out in January-April 1940 In consequence our cases from the B E F contained a very high proportion of men who were reservists or supplementary reservists Secondly we were confining our investigation to men who were regarded as suffering from gastro-duodenal disease whether organic or not, and we were not directly concerned with the various types of reflex dyspepsia Thirdly, Professor Hartfall refers to our " alleged unselected cases " Under the heading of clinical material we give an account of our approach to the problem In the case of B E F troops we were provided with nominal rolls of all men invalided to this country In each hospital we saw each case which had been sent over with a provisional diagnosis of any type of gastro duodenal disease or complication of this, and also all cases which were labelled more vaguely as dyspepsia, &c Our report is therefore correct in stating that we saw " a representative and unselected sample of the dyspeptic cases being invalided home from France " In the case of the local sick seen in the military hospitals we could not follow such a course But we obtained from the medical specialists lists of all dyspeptic cases Again the selection of the material was not ours We feel that if Professor Hartfall will read our report again in the light of the foregoing he will be less inclined to find our conclusions " wholly incomprehensible "

Professor Hartfall also suggests that our findings represent a " wish fulfilment " because they include a high incidence of peptic ulceration Before our investigation it was considered that the high proportion of dyspeptics being invalided from France might mean one of three things—new gastro-duodenal ulceration the breakdown of old-standing ulceration, or a new condition of " soldiers' stomach " Our wish in the matter—as far as we had any—was to find sufficient new ulcer cases to make detailed analyses of the possible ætiological factors of some value Neither of us has the slightest doubt of the importance of psychological factors in gastro-duodenal disease, or of the importance of functional dyspepsia And in every hospital we visited we took the opportunity of discussing these aspects with the consulting psychologists The opinion of the clinicians in the E M S hospitals was uniformly that a dyspeptic case from France was almost always an ulcer case In military hospitals there was a tendency to suspect malingering in all cases (including the gastro-duodenal ones) and at the same time to blame the presence of consulting psychologists in the Army for an increase in supposed neuroses

Our diagnostic criteria also come under Professor Hartfall's criticism In every case the fullest possible history was taken, often occupying 1–2 hours This included details of every job the man had ever had, his economic conditions and his dietetic habits , and it was correlated with his general health and any dyspeptic symptoms at the various stages After this all the laboratory data were examined Admittedly these data were not always as complete as they might have been We then discussed each case in the light of all the information obtained, and our diagnosis was based on a summation of the evidence In almost every case the clear-cut history which we received would have satisfied even the most sceptical that we were dealing with organic disease improvement is said to have taken place Although the diet was preponderantly carbohydrate, on account of the cirrhosis, there were no further clinical symptoms of diabetes This is ascribed to a diminution in the glycogen reserve in the cirrhotic liver, or to a compensatory hypertrophy of the pancreas

Letters to the Editor

ARTIFICIAL SHORTAGE OF DOCTORS

SIR,—It was high time that this subject should be brought to the notice of our profession and of the general public, and you are to be congratulated on dealing with so grave a matter in so judicial a way It is possible to sense that but for your responsible position there was more that you wished to say This fictitious shortage is primarily due to the demands of the Army Medical Service, for the Navy and Air Force seem to have exercised praiseworthy restraint in their demands As you have indicated in your final paragraph it is essential that the requirements of our overseas and home services be considered separately

Overseas forces on active service must be provided with adequate medical personnel under military discipline Are we not entitled to ask, if the Army Medical Service is not guilty of extravagance in the number of medical officers it requires for each type of unit? The establishment of these is said to be confidential and one can understand the reluctance of the Army Medical Department to reveal the voracity of its appetite, but in fact the figures are well known as they appear in those textbooks and manuals which assist officers in their promotion examinations A general hospital of 1200 beds is allotted 34 M O s in addition to a quartermaster and three padres—a generous allowance to say the least Other units are catered for on an equally lavish scale It is a rigid insistence upon this establishment which is threatening to strip civilian medical reserves at a rate which is heading straight for disaster It is permissible to ask why nearly all our best young men put their names down for the Navy or Air Force and unwillingly take the Army when told that the other services are full Among many other reasons is the advice given by friends who joined up earlier " Whatever else you do, don't join the R A M C there are lots of us here and nothing to do "

When we turn to the home front, the extravagance and wastage of personnel could find no better example than that quoted by you—the creation of 12 orthopædic centres in the Army—and yet this is only symptomatic of the whole Taken by itself, however, it is a cogent reason for pooling our resources in both men and equipment, as one illustration will suggest Rehabilitation has been a favourite word of late, but only its fringes have been explored by either civilian or military authorities In the Services when a man is boarded out as unfit he is thrown back into civilian life without ever having been given the benefits of these army centres , such a man with a pittance of a pension and unfit for work becomes a liability and not an asset to the community Surely this economic futility could be avoided by pooling our resources Whether a man be in khaki or dark or light blue he is still an individual member of the community and when sick or wounded is entitled to the same care and treatment as the sick or wounded civilian—neither more nor less Why then in England should he be treated separately ? Matters of service discipline and organisation arise when uniformed patients are treated in civilian hospitals but that has already been solved in the E M S hospitals This pooling of doctors is redolent of State Medicine, and I confess to being apprehensive of recent talk upon this subject, for the times are not conducive to sane and balanced thought upon an indefinite future But if this pooling of our resources is state medicine then I am well on the way to conversion

In spite of what you say this is a clash between rival claimants, not for personal but personnel ends, and as more than one great department of state is involved the final court of appeal presumably is the Cabinet If it wishes to ensure adequate medical attention for every section of the community in the testing times which lie ahead it must move and that right quickly

Harley Street, W 1 R M HANDFIELD-JONES

THE BLEEDING TOOTH SOCKET

SIR,—Many dental surgeons will regret the opening paragraphs in your annotation of Dec 28 (p 814) You appear to imply, although you do not actually say so, that dental hæmorrhage arises through a fault on the part of the dental surgeon, who shirks his responsibility, but this is rarely so Most dentists are only too willing and anxious to treat their own cases of dental hæmorrhage It is a well-known fact that the dentist in nearly all cases is better equipped to do so than the doctor, but serious cases do arise where the coöperation of the doctor and the dentist is essential The patients are responsible for calling in the doctor and they have a perfect right to call in medical aid, particularly if they are panel patients Medical men do not quibble about attending a wealthy patient in the middle of the night for dental hæmorrhage, and often take the case out of the dentist's hands, but if it is a panel patient, and there is no fee, well—that is where the shoe pinches The correct procedure is for the doctor to ring up the dentist at his home, and ask him to attend, and then for the dentist to call in the doctor, if necessary Your statement that hardly any of the cases which give trouble after dental extractions are hæmophiliacs is only partially correct All hæmophiliacs give trouble after extractions, and the greatest possible precautions have to be taken The class which gives greatest trouble is the pseudo hæmophiliac In true hæmophilia we know the male inherits the condition and the female passes it on , she is not herself a true hæmophiliac, but is often a pseudo-hæmophiliac Dental hæmorrhage often arises in females because the extractions have been done during, or immediately preceding the onset of the menstrual period A wise dentist will always make inquiries before proceeding with extractions, particularly multiple extractions, in females

Hæmorrhage usually takes place from the apex of the socket, and is often caused by the disruption of a dental abscess, or granuloma at the apex of the tooth To stitch over the gums of a true hæmophiliac is dangerous, because hæmorrhage would immediately take place from the trauma caused by the needle If the bleeding point is from the gums around the socket, then the actual cautery is very efficient Venom of the Russell viper is also very effective for this, but if the hæmorrhage is taking place from the bottom of the socket, as is usually the case, it is almost impossible to apply this to the bleeding-point, since it is washed away by the hæmorrhage *In my opinion, there is only one* safe, effective and never-failing remedy, and that is the treatment I discovered accidentally about twenty-five years ago, and have published several times in dental journals It is this a hard tampon of cotton-wool, about the size of the *root socket*, is put *into a liquid made up of* equal parts of liquor ferri perchlor , liquor hydrarg perchlor , and glycerin It is then dipped into tannic-acid powder and pressed firmly into the socket, being kept in situ for a few minutes with the end of the finger, and left in for twenty-four hours This black pack contains no free perchloride of iron (which invariably causes sloughing and further hæmorrhage), because the perchloride of iron unites with the tannic acid to form a tannate of iron Tannate of mercury is also formed, and free hydrochloric acid. Anæsthesin (benzocaine) is also invaluable, because it causes a constriction of the walls of the blood-vessels, and this may be added to the tannic acid with advantage

Patients should not be allowed to rinse the mouth after extractions, not even a single mouthful Water weakens the clot, causing a wash-leather surface, instead of a hard glazed surface Mouth-washes for after-treatment are a mistake, particularly hydrogen peroxide or sodium perborate, for these dissolve the blood clot The gums should be swabbed with a mild antiseptic on cotton-wool Patients should be instructed not to suck the gums, or poke the sockets with the fingers Tea should be prohibited Dental hæmorrhage often commences twenty minutes after taking a cup of tea For all known or suspected " bleeders " prophylactic treatment should be prescribed calcium for three days prior to extractions, or injections of hæmoplastin, plus vitamin K I have for some time done extractions for these patients when necessary, after may vary in different people. It is my opinion that Sheehan and Sunderland, whom you quote in your annotation of Jan 18 (p 82), are correct in stating that in cases of mitral stenosis even when fatal there may be no myocarditis, with the proviso that there may be changes in the neuromuscular heart wall we cannot detect or have not detected, though this I personally doubt. When there are recent vegetations (to state the age of a vegetation is not easy) possibly there may then be some myocardial weakness perhaps only passing, yet sufficient to turn the scale adversely.

Naturally as an Englishman I challenge the statement that Mackenzie was the cause of the radical change in our views about the myocardium. The first part of my work on rheumatism in the last century was to prove clinically, pathologically and later experimentally the importance of the myocardium in rheumatic heart disease, and I dare to claim some credit without being derogatory to Mackenzie whose work no-one could harm. William Broadbent and many others in London recognised the importance of the myocardium, among them D B Lees, who joined with me in my first paper (*Med -chir Trans* 1898, 81) on the subject.

Bath. F John Poynton

VAGARIES OF THE PAUL-BUNNELL TEST

Sir,—The value of the Paul-Bunnell test in the diagnosis of glandular fever promises to become a matter of controversy. Whilst there is now a concensus of opinion that a positive agglutination reaction between sheep's red corpuscles and the patient's serum is strong confirmatory evidence that the case is one of glandular fever there appears to be some doubt as to the significance of a negative agglutination test. Bernstein indeed, in a recent review (*Medicine, Baltimore*, 1940, 19, 85), seems inclined to consider that a negative Paul-Bunnell test justifies the exclusion of the diagnosis of glandular fever, but few clinicians would be prepared to go as far as this, for it is undeniable that there are many cases presenting clinical features of this disease in which the test is persistently negative. The situation is well exemplified by the two papers in your issue of Jan 18; Dr Barber reports 8 cases in each of which the test was positive. Dr Fuller reports 5 cases, clinically similar, in 4 of which the test was negative and in 1 positive only to an insignificant degree. Dr Fuller's patients were undoubtedly more ill, and they also differed in the frequency with which Vincent's organisms were found in the throat and in the fact that they were treated with sulphonamides. Otherwise the two series were very similar, in both the patients were febrile, had angina enlarged cervical and axillary glands, and the differential white count showed a percentage increase in mononuclear cells. Clearly there are two possibilities on this evidence, either the clinical and hæmatological picture of glandular fever embraces other diseases which can only be distinguished from true glandular fever by the absence of a positive Paul-Bunnell test, or the Paul-Bunnell test is an inconstant feature of glandular fever capable perhaps of being modified by treatment or of varying with the stage of the disease. It is clearly desirable to decide between these possibilities and consideration of the hæmatological picture in the two types of case appears to give a clue to this end.

Anyone who is familiar with blood smears from this type of case stained with the Romanovsky stains is aware that there may be some difficulty in differentiating between monocytes and the different types of lymphocyte present. Some clinicians may have had the experience as I have, of finding that different pathologists, while agreeing on the figure for the number of mononuclear cells present, differed markedly in the proportion of these cells they assigned to the category of lymphocyte or of monocyte. Nevertheless an examination of the blood-counts in Dr Barber's and Dr Fuller's papers suggests that such differentiation may be worth making accurately. When the numbers of the different types of white cells given for their cases are expressed not as percentages of the total number of white cells present but as the number of such white cells per c mm it will be seen that, while there is no apparent correlation between the Paul-Bunnell test and the number of polymorphonuclear cells or lymphocytes, there is a hint of a correlation between the test and the number of monocytes present. In Dr Barber's series of cases, all of whom showed a positive Paul-Bunnell test, the average number of monocytes per c mm is about 2150, in Dr Fuller's series the average is within normal limits at 520 per c mm. It is perhaps significant that the one case of Dr Fuller's whose serum agglutinated sheep's red cells showed the highest monocyte count of his series. The range of the figures for monocytes in the two series certainly overlap, and thus only allow a tentative suggestion that the difference is significant, but in view of the difficulty of differentiating monocytes from lymphocytes in these cases by the stains in routine use this objection may be resolved when staining techniques giving more sure differentiation are used. On examining the blood-counts from similar cases of my own the same relationship between a positive Paul-Bunnell test and an absolute monocytosis was found in general to hold. One of my cases, already reported (*Lancet*, 1940 1, 1082), is of especial interest. The illness lasted three months and while the differential count expressed as a percentage showed a relative mononucleosis throughout, the differential count expressed as the number of cells per c mm did not indicate a monocytosis until the last month of illness. At the commencement of the illness the monocyte count was 468 cells per c mm and the Paul-Bunnell test was negative, at the end of the illness the figure was 1530 and the test was then positive.

The next step in the investigation of the clinical syndrome now designated under the single title of glandular fever might be the collection of accurate data concerning the association in this condition of monocytosis and a positive Paul-Bunnell test. To this end the blood from such cases should be examined by staining techniques which permit the accurate recognition of monocytes. And to facilitate appreciation of the results thus obtained the common practice of expressing the differential count as a percentage of the total number of white cells should be discarded in favour of expressing the count as the absolute number of cells per c mm. Should the above association be established then it is evident that it will have not only practical value but a considerable theoretical interest as showing a correlation between the increase of a certain type of cell in the blood and the development of a particular serological reaction.

H P Himsworth

University College Hospital Medical School

DEATH ON THE TABLE

Sir,—I was talking to a colleague about the question of resterilisation of the operating theatre after a death has occurred on the table. We were wondering why this was done. Inquiries from nurses sisters, and books have only told me two things:—

(*a*) No one really knows, but it's in the books and has been for years.

(*b*) That some evil spirit leaves the body at death, and desterilises all the equipment.

Is this custom a relic of the surgery of the past century? The "evil spirit," no doubt, is the *Bacillus coli* which is known to permeate throughout the body tissues after death has taken place, but I cannot help thinking that this could be of no practical significance when the body is on the table for such a short time after death.

Has anyone got a really sensible answer to this question?

Chichester John Gordon

BERGSON IN LONDON

Sir,—In the press notices to which the recent death of Henri Bergson have given rise it appears to have escaped attention that the eloquent author of "L'évolution creatrice," some thirty years ago, lectured at University College London. It was perhaps not without significance that the subject of the lectures at what has been satirically, but unjustly, called the Godless College should have been "the nature of the soul." The first of the four lectures was delivered on Oct. 20, 1911, in the botanical theatre of the college. It fell to me as vice-chancellor to preside, and among the large audience were the French Ambassador Sir Francis Goodenough Dr Sadler, Dr Miers, Dr Caldecott and Dr Dawes Hicks. The lecture was delivered in French and gained lucidity thereby, while the subject though recondite was

In the "proved ulcer" cases this was supported either by the evidence of the complications of ulceration, by the laboratory evidence, or even by the objective evidence of abdominal scars. In the absence of confirmatory evidence the cases were labelled as "probable ulcers." To adopt the position which was sometimes urged of "no ulcer without a demonstrable crater" would have been to lose sight of all diagnostic perspective. In this connexion we can only repeat conclusion 12 of our report: "Our experience proved that the sorting of serious case in France for invaliding to this country was very efficient." It is clear, therefore, that we were investigating dyspepsia in the Army as it presented itself in the early part of 1940 in men from the B E F and amongst the local sick. Both of us were impressed by the very small number of neuroses. The evidence which we received did, however, suggest that in the base hospitals in France there was a higher incidence of neurotic cases than was present in our material. A proposed visit to France to investigate cases on the spot was rendered impossible by the military situation. The evidence which we have recently received suggests that the dyspepsia problem now shows a much smaller proportion of organic cases, and an increase in the neurotic ones running parallel with the increase of neuroses in the Army. This is not in the least surprising, and it stresses the need for an accurate diagnosis in the individual case. The conclusions which we have put forward in our report relating to the importance of organic disease in the clinical material which we investigated were confirmed by the experience of the medical officers in the various E M S hospitals, and, with the reservations referred to, by the medical specialists in the Army. We can only report the results of our investigation on the basis of our data. To ask Professor Hartfall to accept these might lay us open to the charge of "wishful thinking."

Harley Street, W 1

REGINALD T PAYNE,
CHARLES NEWMAN

SULPHATHIAZOLE IN CEREBROSPINAL FEVER

SIR,—The results of treatment of cerebrospinal fever with sulphathiazole described by Dr Banks in THE LANCET of Jan 25 will arouse considerable interest and surprise among practitioners who have used the sulphonamide drugs in various infections, including cerebrospinal fever; certain deductions are drawn which are, we feel, not justified by Dr Banks's explanations. Dr Banks says that he regards as "dangerously low" a dosage of 6 grammes of sulphapyridine a day for an adult. It is difficult for the impartial reader to follow his reasons for such an assertion, reasons he discusses in the course of his paper. In the first place, he quotes two cases on this dosage which, "still had meningococci in the C S F after 2½ days' treatment, a thing which never occurred after sulphathiazole in standard dosage." Surely the ultimate ideal of treatment is the cure of the patient with the absence of sequelæ, which anyone would be satisfied to achieve in a week or a fortnight in such an important disease as this! Dr Banks describes two cases to illustrate the fate of patients treated on this scale of dosage. In case 1 the relapse occurred after a dosage of 9 g a day at first and a total of 15 g sulphapyridine and 43 g of sulphathiazole in ten days. Surely this relapse followed the higher dosage as advocated by Dr Banks; it is an error to say that it was the result of treatment on the lower dosage of sulphapyridine previously given for no more than two days.

Dr Banks considers that two days' treatment with sulphapyridine should be enough to eradicate the disease, but he will find it hard to persuade people to believe such a result either possible or necessary, or to convince your readers that the relapse in case 1, as he asserts, was "associated with the low dosage (6 g) of sulphapyridine in the first 2½ days." We have ourselves treated a few cases of cerebrospinal fever and other infections successfully on what Dr Banks terms the "low dosage" and have never regretted it, nor could we have desired better results than we achieved. We have also heard of cases successfully treated by others on similar lines. We are sure practitioners all over the country will endorse our evidence that 6 g a day for the average adult is adequate. If this is so, the prevention of the use of too large doses all over the country would, we feel, contribute to the avoidance of toxic manifestations from this group of drugs. At the same time equally good results would be obtained on the dosage now widely and generally used with such success, dosage which has given clinical success on every occasion in our experience when success could have been reasonably expected and has not been associated with the "danger" which Dr Banks describes.

Basingstoke

PHILIP H WILLCOX,
GEOFFREY CUTTS

HOSPITALS AND THE WAR DAMAGE BILL

SIR,—Some indirect effects of the War Damage Bill now in committee before the House have not, I think, been realised by classes affected by it. Clause 29 deals with "property held for charitable purposes," in which these two categories are included:

(1) The treatment of sickness, disease, or injury, whether physical or mental;

(2) The advancement of education, science, or research.

Category 1 directly concerns the medical profession. Category 2 interests educationists and in particular universities, colleges and teaching hospitals. A parliamentary expert much more skilled than I can claim to be in assessing the effect of proposed legislation, informs me that this clause prescribes that in return for compulsory acceptance of the "concession" of one-third only of the normal contribution (or premium) the War Damage Commission, the members of which are all appointed by the Treasury, may "if they think fit" make a compensation payment, "subject to such conditions as they may in their discretion determine." These conditions could, in the case of a hospital for example, entail rebuilding on prescribed lines in prescribed places; alter the composition of the governing body; control the appointment of staff; destroy the traditions, and impose a large measure of state management. In the case of an educational institution, the commission could, in addition to these activities, vary the curriculum, prescribe the examinations and standards of qualification, and make many other changes, not at present contemplated by the authorities concerned. It is useless to say such things could not happen; these powers are being incorporated in an act of Parliament, and may at any time be exercised.

House of Commons

E GRAHAM-LITTLE

THE RHEUMATIC HEART

SIR,—Over many years I studied rheumatic heart disease closely. No form of heart disease has attracted me more than mitral stenosis, because it is the most important; I have seen it fatal at 4 years and not fatal at 70. I have often directed attention to the question whether advanced mitral stenosis might result from one attack of cardiac rheumatism or must be the result of many slight attacks. Indeed this type is more suggestive of the rheumatoid changes in the fibrous tissues of the spine and other joints than any other form of heart disease. Of this I am certain—a case of long-standing mitral stenosis may after death show no myocarditis as seen by microscopic examination, and the strain on the right heart with its complications has probably been the cause of death. I am equally certain that small vegetations on the mitral valve with little or no myocardial damage are, as one would expect, not likely much to embarrass the action of the heart. This is shown by the almost complete recovery which I have observed many times and watched over for years. On the other hand, if these vegetations are associated with severe myocardial disease and damage to the mitral ring the course may be rapidly downward. This is one reason why the modern teaching that a systolic mitral murmur is not important is wrong, for this murmur may lead to the discovery of the real state of affairs.

When one finds a patient of 60 or upwards with mitral stenosis there are various factors to be considered. Is this the result of a single attack in early life followed by a very slow contraction of the valve with which the heart keeps pace? Is it the result of many slight attacks spread over many years? Is it the result of an attack of cardiac rheumatism unusually late in life, and possibly overlooked? Has the patient always lived a guarded life, or, for example, lived at the top of a steep incline? Do the fibrous tissues of one individual differ from those of another in their tendency to contraction? We know certainly that the power of the heart muscle from childhoo calling up of younger men and by the greatly increased demand for medical attention to the civil population during the winter months —Captain MARGESSON replied Applications for the temporary release from the Army of medical officers to meet the needs of the civil population have been, and will continue to be, sympathetically considered, but it must be remembered that the Army can ill spare their services

Sir F FREMANTLE Does the Minister realise that something like 8000 medical officers have been taken from civil services to the forces although civil needs are greater now than they were in normal times, because of bombing casualties ? Is he aware also that a very large number of Army medical officers have very little to do, while the civil services offer a very great deal of work that they can do ?

Mr RHYS DAVIES Is the Minister keeping in touch with the Ministry of Health on this problem ?—Captain MARGESSON Yes

Medical Referees

In reply to a question Mr O PEAKE, under secretary to the Home Office, said Ophthalmologists have been appointed as medical referees under the Workmen's Compensation Act for the sheriffdoms of Lanark, Lothians and Peebles, and Renfrew Medical referees to deal specially with cases of scheduled diseases (including dermatitis) have been appointed for the sheriffdoms of Lanark and Renfrew The Minister appreciates that it may be desirable to strengthen the panels of medical referees in these and other areas by more extensive appointments of specialists, and he will be very glad to consider representations in regard to any particular area, but experience shows that it is extremely difficult to secure the services of suitable specialists as referees under present conditions

Health Services at Newquay

Mr P L HORABIN asked the Minister of Health whether he was aware of the unsatisfactory state of the health services in Newquay, and whether he proposed to take any action to improve them, in view of the large increases of the population due to the billeting of official evacuees in the town.—Mr M MACDONALD replied I am aware of the position in the district The county health services have recently been strengthened by the appointment of an additional assistant county medical officer, the seconding of six school-nurses to the county by the London County Council, and the expansion of the district medical service Local health services have been improved by the establishment of a general sick-bay and of a special sick-bay and clinic for skin cases Further steps at present under consideration include the appointment of another assistant county medical officer, part of whose time would be devoted to this area, and the provision of additional hospital accommodation for cases of infectious disease

Gastro-duodenal Disease in the Army

Sir FRANCIS FREMANTLE asked the Secretary of State for War what percentage of cases invalided from the British Expeditionary Force to this country were suffering from gastro duodenal disease, and whether strict instructions would be given to recruiting boards to reject men with a history of organic dyspepsia and save the loss and inefficiency caused thereby to the Army —Captain MARGESSON replied The percentage of patients suffering from gastro-duodenal disease among hospital cases invalided from the British Expeditionary Force was 11 76 As regards the second part of the question, strict instructions on the point have already been given to recruiting medical boards —Sir F FREMANTLE Is the Minister aware that these instructions are not very effective, and that these men are a very great cause of trouble, loss of morale and inefficiency in the Army ? Is it not a great waste of Army effort, and should not an effort be made to bring the facts home to recruiting boards ?—Captain MARGESSON I will press the matter in that direction.

Mr C STEPHEN Will the Minister see that in cases where men are weeded out pensions will be given ?—Captain MARGESSON That is a matter for the Ministry of Pensions

Inoculation in the Services

Mr W LEACH asked the First Lord of the Admiralty whether he was aware that a number of men in H.M S *Colombo* had been deprived of shore leave for refusing inoculation, and whether, in view of the fact that the *reports* on the health of the Navy disclosed the occurrence of a considerable number of cases of typhoid fever in inoculated men, he would follow the precedent set by the Admiralty in the last war when similar cases of deprivation of leave occurred and permit objectors to inoculation to have leave in the same way that inoculated men were allowed it —Sir VICTOR WARRENDER, parliamentary secretary to the Admiralty, replied Men who have declined inoculation against a particular disease are by Admiralty order precluded from receiving shore leave at places where that disease is liable to be contracted This is a precautionary not a punitive measure, and in other places no restriction is placed on leave I am aware that a number of men in H M S *Colombo* have refused inoculation and have, therefore, been refused shore-leave at various places The rule mentioned above was introduced in 1916 I can find no instance of any exception to it After careful consideration I do not feel able to authorise any exception now in view of the importance of taking every precaution to prevent the introduction of disease on board one of H M ships, especially in war time

Reinforced Flour

Sir ERNEST GRAHAM LITTLE asked the Parliamentary Secretary to the Ministry of Food if he still proposed to add to the flour for the reinforced loaf, described in the debate on July 18, a certain undefined proportion of a calcium salt, whether he was aware that a recent research based on experimental and chemical data and conducted at the Liverpool Institute of Research threw doubt upon the assumption that there was any general deficiency of calcium in the people's diet, and indicated that there was danger in increasing the calcium content in the manner proposed —Major LLOYD GEORGE replied The answer to the first part of the question is yes As regards the latter part of the question, the Minister is advised that the results of the research work referred to are under consideration on behalf of the Medical Research Council, but that it already appears that there are reasons for mistrusting the conclusions drawn from the Liverpool experiments

Mr LEACH Will white flour unadulterated with vitamin B and calcium salt be available after the fortified white flour is put on the market, and will the fortified white flour be labelled to show that chalk and a chemical substance have been mixed with it ?—Major LLOYD GEORGE The decision announced on behalf of the Government in the House on July 18 concerned the addition of vitamin B_1 and a calcium salt to white flour used for bread making No decision has yet been reached on the question of similarly fortifying all white flour

Convalescent Homes for Seamen

Miss E RATHBONE asked the Minister of Health whether he was satisfied that there was sufficient provision of convalescent homes for merchant seamen and trawlermen, whether he was aware that many of them, especially from the trawlers, had to go straight back to their ships from hospital, how many of such homes existed, and whether the number could be increased or other convalescent accommodation provided —Mr MACDONALD replied Apart from the convalescent accommodation specially provided for this class merchant seamen and trawlermen who are casualties are treated in the emergency hospitals and convalescent homes Approximately 100 of the latter have been opened under the Emergency Scheme and others will be available later The question of admitting merchant seamen and trawlermen who fall sick or require treatment for other reasons into these convalescent homes is under consideration

Imported and Non-essential Drugs

Sir FRANCIS FREMANTLE asked the Minister what steps had been taken to limit the prescription by medical practitioners of non-essential imported drugs, and the sale of such drugs as ingredients in proprietary medicines, and to suggest alternatives produced in this country —Mr MACDONALD replied A defence regulation has been made on this subject and its details will be published in the course of the next few days

Gas Helmets for Babies

In answer to a question Mr HERBERT MORRISON said that his department had issued about one and a quarter million anti gas helmets for babies

Transfers of Panel Patients

Mr T E GROVES asked the Minister whether he would now arrange that any panel patient whose chosen practitioner had joined the forces might forthwith transfer to the list of any remaining practitioner willing to accept him, without regard to any unofficial scheme for the protection of practices which might be operating in the district —Mr MACDONALD replied In view of the very general participation of insurance practitioners in these schemes and the importance of safeguarding the interests of practitioners who have undertaken war service, I see no sufficient reason for action never obscure Professor Bergson trounced the popular doctrine of psychophysical parallelism, holding "that we obtain through consciousness a metaphysical knowledge of mind" Among his contentions were—"that change and movement are in reality simple and that state and rest are composite" Again, "that it is in pure duration that the substantiality of the soul consists," and "it is by intuition that we obtain knowledge of the mind" These may seem hard and dark sayings to those brought up on Bain and to those who refer the psychical life to cerebral activities They may perhaps find partial consolation in Bergson's concession "that although the psychical life in itself may be altogether distinct from the cerebral processes, it is upon the brain that our adaptation to the immediate situation, our mental equilibrium depends"

The charm of the lecturer, which had fascinated huge fashionable audiences at the Collège de France, won the sympathetic reception of his London audiences The whole trend of the theme was in harmony with the teaching of Arthur Balfour in his philosophical excursions "towards a more idealistic interpretation of the universe," or, as Wundt was forced to admit, in "these ultimate questions of psychology we must appeal to metaphysics for an answer"

Regent's Park, N W 1 W J COLLINS

PARTING OF THE WAYS IN DIET

SIR,—The remarks of Prof V H Mottram under the above heading are very apposite Recently we have seen four cases of scurvy in adults in this hospital and one case of pellagra There can be little doubt that a considerable portion of the population is not getting an adequate vitamin intake now The present policy of allowing foods of high vitamin value to become very expensive, and then fixing their price above what the majority of the population can afford, is certainly not a sound nutritional policy, whatever other merit it may have In this hospital we are at present exploring the possibility of giving capsules containing a concentration of vitamins to all patients admitted here I feel there is every justification for this for the next three months at least, unless there is a rapid change in the country's policy towards the equitable distribution of all protective food-stuffs

Central Middlesex County Hospital H JOULES

"E Y D"

SIR,—You might like to tell your peripatetic correspondent of Nov 9 (p 607) that I think instead of saying "James Bovell," he should have written "Egerton Y Davis" or "E Y D, Jr" Osler himself told me how he wrote articles over that name

New York Academy of Medicine ARCHIBALD MALLOCH

*_** Our correspondent writes "Yes, I was wrong and was thinking of 'E Y D,' but being in the North Sea couldn't look it up Somewhere in Harvey Cushing's 'Life of Osler' is a picture of an agenda paper on which Osler had written 'James Bovell' about 30 times He was, of course, one of Osler's early inspirers, an enthusiast who forgot all about his patients when playing with his microscope I suppose Osler helped himself to get out of a dull meeting and go back to his golden days by scribbling thus, but that's a very different thing to having a double on whom to heap one's sins" The convenience of "E Y D" (Y stands for Yorick) to Osler was that after his indiscretions he could be safely put out of the way Osler wrote in a preface to one of these pseudonymous papers " he (E Y D) was drowned in the Lachine rapids in 1884, and the body was never recovered "—ED L

MEDICAL SERVICE IN CHINA

SIR,—It is hoped to send a fully equipped ambulance convoy of some fifty or sixty members of the Friends Ambulance Unit to Central China as soon as possible, and the Foreign Office has approved of the expedition A number of doctors will be required and it is hoped that the convoy will comprise a mobile operating team Qualified men of British nationality who would like to join the convoy should apply to me

ANDREW MORLAND,
Chairman of the Medical Subcommittee,
135, Harley Street, W 1 Friends Ambulance Unit

CHILLY SWEEPER

SIR,—I agree with Dr Clifford Allen—there is something wrong, and not only in Harley Street On the main road in my own district I recently observed as I was passing by on the other side, a man lying half dead with his clothes stripped off his back He had obviously been attacked and seriously injured, and he was suffering gravely from wounds, shock and exposure Surely there is some way of seeing that poor unfortunates like this should get some attention, instead of being left to die on the road? Something ought to be done by somebody

Jericho ADAM LEVITE

Parliament

IN spite of a general desire to make as speedy progress as possible with the War Damage Bill, the most important measure of the present session, the House of Commons found time to give a whole day last week to the consideration of a select committee's report on the conduct of one of its own members, and to a debate on the action of the Home Secretary in suppressing two newspapers The arraignment of Mr Boothby, who has taken a prominent part in the political arena for a number of years, and who had just placed his feet firmly on the ladder of advancement by his appointment as parliamentary secretary to the Ministry of Food, was a task for which neither the Prime Minister nor the House as a whole had any relish But in view of the verdict of the select committee, arrived at after the most searching inquiry, there was no alternative Mr Boothby was allowed the fullest opportunity to give his reasons why he dissented from the select committee's findings and then the curtain was rung down as quickly as may be on an incident which all members of the House will try to forget Mr Herbert Morrison found it fairly easy to dispose of the attack made on him by a very small group of members for suppressing the Communist journals, the *Daily Worker* and the *Week* Normally the present Home Secretary would have been the first himself to challenge any attempt to interfere with the freedom of the press, but he had no difficulty in proving that the times are not normal, and that these two newspapers by their persistent attempt to obstruct our war effort had left him no option but to stop their publication The majority—323 votes to 6—by which the opposing motion was negatived demonstrated the overwhelming support in all quarters of the House for the repression of anything which imperils our war effort The remainder of the week's sittings of the House of Commons were taken up by a detailed examination in committee of the earlier clauses of the War Damage Bill The House is passionately anxious that the bill when it becomes an act shall really bring a substantial measure of help to those whose property has been bombed, and particularly to the small house-owner In practice however this is not at all easy, and as the debate has proceeded a fear has been growing that injustice and hardship may result from the decisions of the War Damage Commission The Chancellor of the Exchequer frankly admitted the difficulties and complications of the position, but assured the House that the desire of the Government is to do the fair thing

QUESTION TIME

Medical Prisoners of War

Prof D L SAVORY asked the Secretary of State for Wa what steps were being taken to facilitate the repatriation o medical officers serving in His Majesty's forces, and no captives in Germany —Captain H D R MARGESSON replied The German government have been informed that Hi Majesty's Government are ready to repatriate the Germa medical personnel who are entitled to repatriation under th Geneva Convention of 1929, if the German government wi also conform to the terms of the convention as regards Britis medical personnel in their hands The matter is being activel pursued, but a satisfactory settlement has not yet been reached

Artificial Shortage of Doctors

SIR FRANCIS FREMANTLE asked the Minister if he woul consider the seconding of medical officers from the Army, wit arrangements for their instant recall in case of need, to relie the excessive demands made on medical practitioners by th work on serums, vaccines and toxins was written in collaboration with Professor Eyre, who pays tribute to the spadework which Bosanquet never spared to ensure meticulous accuracy in his premises, a feature of which his easy polished writing gave little hint In 1937 he published "Meditatio Medici," a book informed with his wide culture and tolerance

He died on Jan 24, at the age of seventy-four During the last few weeks of a distressing illness nothing was more in evidence than his innate gentleness and courtesy, which seemed to show themselves more and more as his bodily strength grew weaker Indifferent to his own feelings and to the consciousness of failing powers, he thought only of those around him and of how he could still be to them the kindly and gracious host that he always was

R A Y writes Bosanquet did not seek popular acclaim, or strive after financial success He brought a keen and critical acumen to the study of disease, which was almost too exacting for the mutable criteria of modern medical science He had an absolute conception of right and wrong He would sacrifice his own interests where he felt by making such a protest he could achieve what he regarded as correct and rectify a seeming injustice It was perhaps a misfortune that he eventually turned to clinical medicine rather than to its experimental and laboratory problems He was a philosopher, a thinker and a student rather than a profound clinician It was probably because his sympathies were great and his kindness of heart impelling that he was attracted to the study and treatment of the sick patient With such a character, it can easily be recognised that he was a loyal colleague and a source of strength to any hospital committee His double first at Oxford in literæ humaniores was apparent in his conversation and in all he wrote, for his words were well chosen and apposite He was a wit in every sense of the word—quick incisive and even caustic in repartee on occasion—but he was never unkind His most severe mot would be delivered slowly and with a disarming smile, which left no possible sting I remember in the last war we both had house-physicians of far Eastern origin In comparing notes, Bosanquet told me he thought that he and his house-physician esteemed each other, but did not always quite understand one another's English

ELIZABETH HURDON

CBE, MD TORONTO, FACS

IN 1925 the London Association of the Medical Women's Federation decided to develop a scheme of controlled research in the treatment of uterine cancer by radium at four hospitals staffed by women and Dr Hurdon was appointed as director to coordinate methods and to analyse and record results In 1929 the four clinics were fused into one unit and the Marie Curie Hospital was founded at Hampstead Under Dr Hurdon's direction the results achieved there, first with radium alone and later with X rays were, in the words of Dr Henri Coutard, among the best in the world

Elizabeth Hurdon was born at Bodmin, the daughter of John and Anne Coom Hurdon, and she died at Exeter on Jan 29 She went to school in Canada and qualified in medicine from the University of Toronto in 1895 She went at once to Baltimore where a post at an evening clinic for working women was awaiting her This job paid her living expenses and left her free for what she really wanted—postgraduate work in the pathology department of the Johns Hopkins, under W H Welch But soon H A Kelly, head of the department of gynæcology, offered her a more regular appointment at the hospital and she was able to give up her outside work After three years she was officially recognised by the university and became an assistant and later associate in the department of gynæcology She obtained her F A C S in 1913 In 1916 she was granted leave of absence and volunteered for service with the R A M C She served in Malta and Salonika where she was at one time in charge of the dysentery camp of the 63rd General Hospital She was demobilised in 1919 and returned to the Johns Hopkins where her post had been kept open for her But family affairs forced her to resign the following year and return to this country, where for five years she led what she deprecatingly called the life of a lady of leisure Without a hospital appointment there did not then seem to be any opening for a gynæcological surgeon, and though in an emergency she went to the University of Liverpool as a temporary lecturer in pathology she did not find in general pathology the proper outlet for her powers The Marie Curie scheme gave her the opportunity she was seeking, and after a round of visits to pioneer centres of radium therapy she began her new work She retired in 1938 and was awarded the C B E in the same year Her all too brief retirement was filled with travel and gardening

The portrait is from the cover of the *Medical Women's Journal* (Cincinnati) for September, 1936

THOMAS JAMES MORTON

M B CAMB , SURGEON LIEUTENANT, R N V R

Dr Morton was killed last month in a dive-bombing attack on a cruiser in the Mediterranean He was 29 years of age and the only son of Dr John Leyden Morton and grandson of Dr Thomas Morton, who both practised in West Hampstead He was educated at St Peter's School Seaford, at Marlborough College, and at Clare College, Cambridge He obtained an entrance scholarship to Charing Cross Hospital and took his conjoint qualification in 1936 The same year he also graduated M B Camb He was house-physician to Dr Gordon Holmes and house-surgeon to Mr Norman Lake He was appointed medical officer to the Hull and Sculcoates Dispensary and he held this post until he was called up for service with the R N V R shortly before the outbreak of war He married Miss Patricia Smith of Hessle, near Hull

Barrie Edinburgh

THOMAS VINCENT DICKINSON

M D LOND , M R C P

Dr Vincent Dickinson who died in London on Jan 21 in his 83rd year, was the son of Dr Thomas Dickinson who practised in Chelsea He was educated at King's College and St George's Hospital from which he qualified in 1879, taking high honours later at the London M B and M D After spending some years in house appointments he got on the staff of the Chelsea Hospital for Women and settled in the neighbourhood of Sloan Square, where he remained throughout his life Of a quiet retiring disposition he was a man of wide interests and deep sympathies, which soon became apparent to those who were privileged to know him For many years he was associated with the Italian Hospital in London , his knowledge of Italian caused him to take an active part in the development of cultural relations with Italians resident in London and he was one of the leading spirits who made the Anglo-Italian Literary Society a common meeting ground for Italians and British lovers of Italy For his services to Italians during the last war he received special mention and was made commander of the Order of the Crown of Italy Medieval medicine had a fascination for him and he also took an interest in City life, past and present He was master of the Apothecaries' Company in 1925–26 One of the outstanding events of his term of office occurred when, accompanied by the wardens he attended at St James's Palace to confer upon the Prince of Wales, afterwards King Edward VIII, the honorary diploma of the society —the highest honour which the Society of Apothecaries can confer A detailed description of the society's armorial bearings also came from his pen In 1892 he married Beatrice, daughter of Captain S H Evens, Royal Fusiliers, who survives him with a son and daughter

Obituary

PENDRILL CHARLES VARRIER-JONES

KT , M A CAMB , F R C P

Sir Pendrill Varrier-Jones, director of Papworth Village Settlement, died from a heart attack on Jan 30 within a fortnight of the silver jubilee of the foundation of the colony which he started at Bourn and later moved to Papworth Papworth was his life's work, but he was always seeking new activities and at the time of his death he was planning to add teaching to his other work Only an hour or two before his death he wrote a long letter to Sir Walter Langdon-Brown enthusiastically describing his new scheme He wanted to hold a course at Papworth on the diagnosis and treatment of tuberculosis in which special attention would be given to the sociological and economic aspects of the disease He had drafted an announcement of the course to appear in our columns We can hope that the scheme may still fructify as a memorial to a pioneer in the restitution of the tuberculous to independence

Varrier-Jones was born at Troedyrhiw, Glamorgan, the son of Dr Charles Morgan Jones, and he was a Celt, with *all the Celt's fire and imagination* and with the long black hair and gestures of an impresario He was commonly known as the Pendragon, and this *nick-name* later became the trademark of the Papworth *goods* He was educated at Epsom College and St John's College, Cambridge, where he was a foundation scholar and prizeman He obtained a first in the natural sciences tripos in 1905 and qualified from St Bartholomew's Hospital in 1910 While acting as a temporary tuberculosis officer for Cambridgeshire in 1914 he was impressed with the futility of advising the tuberculous workman to find a light job in the open air and eat good nourishing food As Kingston Fowler was later to say, " a working man has no time to be an early case of pulmonary tuberculosis " Varrier-Jones's reaction was to start his village settlement and among his supporters in the early days when help was most urgent were Clifford Allbutt, Sims Woodhead whose name is commemorated in the laboratory at Papworth, and Sir Humphry Rolleston, *who only gave up his chairmanship of the settlement* a few months ago Outside Papworth Varrier-Jones also served the handicapped as chairman of the rehabilitation committee of the International Union against Tuberculosis, as a member of the Central Council for the care of Cripples, and as honorary consulting tuberculosis officer for Cambridgeshire

Of his " great preceptor " Dr J B McDougall, medical director of the British Legion Village at Preston Hall, has written Few men have accomplished so much in so short a time In twenty-five years Varrier-Jones saw the birth, growth and development of a scheme which bridged the gap between medicine and industry in a way which was original in conception and successful in practice The Papworth " experiment " has long passed the experimental stage and has been emulated with more or less success in this and other countries, but with very few exceptions the results have never been comparable to those which Varrier-Jones achieved in the place which he himself created There was never any doubt that his administrative abilities exceeded his clinical accomplishments, though it can never be said *that Papworth failed to concentrate on research and on* modern methods of treatment But he had himself little time left for the detailed work which clinical examinations and research work involve That he succeeded *in creating a large sanatorium and industries* was in itself a tremendous task, but that he was able to obtain the capital which made his extensions possible year by year singled him out as a great figure in medical socio-economics I know well the strain which this made on him It was his own personality which made Papworth possible and I doubt whether he would have reached the same pinnacle of fame had he been forced to administer a similar unit under the restrictions and guidance *of any local authority From the inception* of the small settlement at Bourn, he remained in supreme control, dictating policy to the minutest detail He threw himself into the ramifications of the various industrial departments with the ease of a master of industry, and was quick to detect the markets which were waiting for the products of disabled men and women In his position of isolation as the leader of a new conception in medicine he had little time for committees, conferences and the like In addition to Papworth he was called upon at different times to advise and organise new *schemes in other parts of the country*—at Enham, where he built up successful markets for the industries run by patients suffering from nervous diseases , at Peamount Sanatorium, Dublin, where a promising settlement was set going some ten years ago , and at Preston Hall where he reorganised the institution at a time when the British Legion assumed administrative control Abroad, his services were in constant demand and I remember visiting with him Claire Vivre, the new settlement in the Dordogne—a scheme which was killed almost at its inception by the intervention of political prejudice After a brief tour of the institution, houses and workshops he suggested that two years should bring the scheme to a conclusion I thought it might last a little longer, but as usual he was right " If only they would pay attention to principles and leave details to look after themselves " was his comment

We have lost a leader in tuberculosis thought and an administrator of superlative ability

WILLIAM CECIL BOSANQUET

D M OXFD, F R C P

Dr Cecil Bosanquet was leisurely and learned His students enjoy remembering his ward rounds , the questions he dropped were never pressed home on the faltering, and the replies, however remarkable, were courteously if quizzically received He never deliberately made anyone look a fool, but he made all feel that medicine was a vast, largely untravelled field, and that perhaps the last word had not been said in the latest textbook after all Students learned from him not facts so much as an attitude to the work they were beginning His consideration for the patient always transcended *the convenience of the teacher* And his aphorisms, punctuated by his gentle sniff, were hugged and carried away, to be repeated round the medical school

Elliott & Fry

He was the son of Admiral G S Bosanquet and was educated at Eton, where he was a King's scholar, and New College Oxford, where he *took a double* first in greats in 1889 He was a fellow of his college from 1890 to 1897, when he took his B M and D M He became F R C P in 1904 He was appointed physician to *Brompton and* Charing Cross Hospitals and physician to the London Lock Hospital and had held a majority in the R A M C (T), from which he had retired He was also consulting physician to the North-West Frontier Force of India, and physician to outpatients at the Victoria Hospital for Children

Bosanquet was *not* gregarious Some of his colleagues worked with him for more than twenty years without learning anything about his personal life, or even knowing where he lived or what he did in his spare time He gave the impression of being a man with a fine brain who had lost his enthusiasms He would tease his colleagues about theirs, and then apologise very kindly and make amends by offering wise and critical advice He was jealous of the good name of Brompton Hospital, and the *Brompton Hospital Reports* which were begun in 1932, were his idea *He became senior* editor and made happy comments in the margins of the galleys submitted to him *When he left the active staff the* lay board of management invited him to join them , he accepted and attended meetings punctiliously He seldom thought a matter worth taking a stand over—his usual attitude was *expressed* in a tolerant shrug—but when he did he was not to be shaken His standards of justice admitted of no compromise

Most of his written work was on underlying principles rather than on *patients and he edited* successfully the thirteenth edition of " Green's Pathology " An early

On Tuesday, Feb 18, at 2 15 P M at the section of comparative medicine of the Royal Society of Medicine Prof T J Bosworth, D V S M, Mr Frederick Blakemore, D V S M, Dr H H Green and Dr M Murray will open a discussion on fluorosis in man and animals At the same meeting Dr Eugene Nassau will read a paper on the culture of tubercle bacilli from laryngeal swabs The section of orthopædics will meet on Saturday, Feb 22, at 11 30 A M, at Bothley's Park War Hospital, Chertsey, Surrey, when Mr W Rowley Bristow will open a discussion on injuries to peripheral nerves On Tuesday, Feb 25, at 2 30 P M, Dr C P Symonds will deliver his postponed presidential address to the section of psychiatry He will speak on the neurological approach to mental disorder

The Davyhulme Military Hospital Medical Society held its inaugural meeting on Jan 30 when Major R W Fairbrother read a paper on cerebrospinal meningitis The object of the society is to encourage medical men and women in all the services (including civilian) to meet together to discuss problems of common interest and membership is open to any medical man or woman in the area The next meeting will be held at the hospital on Thursday, Feb 13, at 3 P M when Lieut Colonel W E Underwood will read a paper on gunshot wounds in the field Further information may be had from the hon secretary, Major William Brockbank, Military Hospital, Davyhulme, Nr Manchester

Births, Marriages and Deaths

BIRTHS

DOBBIN —On Jan 31, at Crondall, Hampshire the wife of Dr Leonard Dobbin—a son

HALLAM —On Jan 29, at Reigate, the wife of Dr H N Hallam—a son

LYSAGHT —On Jan 30, at Bridgend, Glam, the wife of Mr A C Lysaght F R C S —a son

PATERSON —On Jan 24 at Kingston Ontario, the wife of Captain John F Patterson R C A M C, of Little Baddow, Essex—a son

MARRIAGES

BISSET—ALEXANDER —On Jan 23 at Perth, George Maxwell Fraser Bisset, M B to Arlette Myrtil Alexander

BONE—MACLEOD —On Feb 1 at Ealing, Alan W Bone F R C S, younger son of Dr J W Bone, to Sheila Margaret MacLeod

KERSHAW—COWELL —On Jan 23, at Bramhall William Edgar Kershaw, M B Manc, Surgeon Lieutenant R N V R, to Maureen Alexa Clayton Cowell

MOYNAGH—MARTIN HARVEY —On Feb 1 at Beckenham Kent, Kenneth Desmond Moynagh M R C S, Captain R A M C, to Drusilla Wendy Martin Harvey

DEATHS

ACKERY —On Jan 29, Edward Faulknor Ackery M R C S late medical registrar Royal Dental Hospital London aged 65

ARMSTRONG —In January, by enemy action Keridwen St Valentine Armstrong, M D Lond, wife of Dr J V Armstrong

CHAPMAN —On Jan 31 at King's Somborne Charles William Chapman, M D Durh M R C P late of Wimpole St aged 97

DUN —On Jan 31, at Shrewsbury, Robert Craig Dun, M B Edin, F R C S late of Liverpool

EVANS —On Feb 2 at Herne Bay, Robert Cecil Turle Evans, M B Lond, aged 69

FORREST —On Jan 28 at West Manse, Auchterarder, Robert Sibbald Forrest, M B Edin aged 76

GORDON —On Feb 2, at Bedford Edward Gordon, M C, M B Aberd

HURDON —On Jan 29, at Rockleigh, Exeter, Elizabeth Hurdon C B.E., M.D Toronto, F A C S

MCFADYEAN —On Feb 1 at Hindhead, Sir John McFadyean, M B Edin, M R C V S, aged 87

MEAD —On Jan 28 M Theophilus William Mead, M R C S, of Portsmouth

PRATT —On Feb 4, Edward Frederick Pratt, M B Durh, of Lansdowne House Berkeley Square W aged 74

REES —On Jan 29, at Swanage, William Arthur Rees M D Lond, F R C S

ROBINSON —On Jan 29, at Worthing, Florence Ada Robinson, L R.C.P E

SPROTT —On Jan 29, Andrew Sprott M B Glasg, of Appleby, aged 74 years

VARRIER JONES —On Jan 30 at Papworth Hall Cambridge Sir Pendrill Varrier Jones M A Camb F R C P

HAMILTON ALISON M M B Edin D P H asst pathologist at the Royal Infirmary Sunderland

Notes, Comments and Abstracts

MIGRATION OF INSURED PATIENTS

IMMEDIATELY before the outbreak of war the Ministry of Health issued a circular to all insurance committees, pointing out that some latitude would have to be allowed as regards the maximum number of insured persons permissible on practitioners' lists The minister approved an addition of 500 to the prescribed maxima In the 16 months which have passed since then the demands of the military authorities for practitioners have become more and more clamant The London Insurance Committee has been particularly affected and have appealed to the Central Medical War Committee to avoid calling up practitioners from districts which have been particularly affected by aerial attack The C M W C realise that London's new health problems make a special demand on practitioners and say that in balancing the conflicting demands of the civilian service and of the military authorities the insurance committee's point of view will be borne in mind But it has been suggested that, in view of the number of persons being evacuated from London, it should not be difficult to release insurance practitioners for military service, and that since they have lost many private patients they could doubtless assume responsibility for additional numbers of insured patients Some evacuees, however, return to their home districts within a short time The panel lists of doctors in the evacuation areas are therefore misleading, because some of their patients who have been officially transferred to provincial doctors have returned to town, while others, living in reception areas have not troubled to remove their names from their town doctor's list Thus the names on the lists of doctors in evacuation areas are in excess of the number of patients likely to call them in There is little danger, therefore, that these doctors will be overworked if they are permitted to take on patients in excess of the normal maximum

Another difficulty arises out of the release of assistants, particularly where the practice is capable of being administered under the protection of practices scheme If a principal has been allowed to accept say, 1000 extra patients by virtue of his employing a permanent assistant, he cannot obtain relief under the scheme if the assistant is called up If the principal himself is called up the practice can come under the scheme and the assistant can become an acting practitioner and accept such of the principal's patients as apply to him for treatment It is becoming increasingly difficult to obtain assistants, particularly in areas susceptible to aerial attack, and the London committee feel that they will shortly have to ask for a further relaxation of the limit placed upon the number of insured patients for whom a practitioner may assume responsibility They think, too, that where an assistant is called up and the principal is unable to obtain the services of another assistant arrangements might be made for other local practitioners to agree to give help so that the principal can retain his full list of patients This arrangement would have to be administered with caution so that it did not offer an excuse for principals to dispense with the services of their assistants while expecting to retain a list in excess of the permitted maximum Meanwhile the London committee have applied in three or four cases for special maxima to be allowed to practitioners in the affected areas

PAGET TELLS HOW HE DISCOVERED TRICHINELLA

IN Stephen Paget's memoir of his father is an account in Sir James Paget's own words of his discovery in 1835 of the *Trichina spiralis* during his first year in the dissecting room at Bart's My share, he writes, was the detection of the "worm" in its capsule, and I may justly ascribe it to the habit of looking-out, and observing, and wishing to find new things which I had acquired in my previous studies of botany All the men in the dissecting-rooms, teachers included, "saw" the little specks in the muscles, but I believe that I alone "looked-at" them and "observed" them no-one trained in natural history could have failed to do so The discovery, he goes on, had a memorable consequence,

ALEXANDER LEWIS McMILLAN

M D GLASG

Dr A Lewis McMillan who died at Bridge of Weir on Jan 21 graduated at Glasgow University in 1887 He took his M D two years later and started to practise in Newton-on-Ayr, but he soon returned to Glasgow where he practised for nearly fifty years He early became interested in ophthalmic surgery and in 1892 was appointed assistant to Freeland Fergus at the Glasgow Eye Infirmary This was the beginning of a long association with that institution which lasted until he retired from the post of surgeon in 1918 In 1921 he became visiting oculist to the Glasgow fever hospitals and from 1927 till his retirement from medical practice in 1937 he was attached to the Glasgow public health department in connexion with pensions for the blind He maintained a close interest in the affairs of the Lansdowne Church and did much benevolent work in a quiet and unostentatious way His wife died some years ago but he is survived by two sons and three daughters

Medical News

Royal College of Physicians of London

At a comitia of the college held on Jan 30, with Sir Robert Hutchison, the president, in the chair, the following representatives of the college were elected Sir Charles Wilson, Dr H L Tidy, Prof J A Ryle and Prof H P Himsworth on the British Medical Association Medical Planning Commission, Dr A Feiling on the council of the Queen's Institute of District Nursing, Dr Stanley Barnes on the court of governors of the University of Birmingham, Dr P Hamill on the advisory committee of the Ministry of Health to compile a war emergency formulary Dr W E Lloyd was appointed an examiner in pathology and Dr G Roche Lynch was appointed an examiner in public health

The following candidates, having satisfied the censors' board, were admitted to the membership —

J B Arthur M B Edin , J D Ball, M B Lond , T E D Beavan, M B Birm , A J Bernfield, M B Lond , Stanford Cade, F R C S , W E Clarke, M B Lond , Constance E Field, M D Lond , M O J Gibson, M B Camb A G Heppleston, M B Manc H M James, M B Camb , R B Magill, M B Belf , R H Mole, M B Oxf , N V Nene, M B Bombay , Elizabeth H Rosenberg M B Lond , Gerard Sanderson, M B Lpool S P Sinha, M B Patna G R Steed M D Lond , C H C Upjohn, M B Camb , C K J Vautier, M B N Z , Celia K Westropp, M B Oxf

Licences to practise were granted to 177 candidates (155 men and 22 women) who have passed the final examinations of the conjoint board and complied with the by laws of the college The following are the names of the successful candidates —

J P Adlam, Bennie Alexander A J C Allen G J Amiel, A W Anderson C M Arango, Alfred Arnstein, M W Arthurton, Walter Aspinall, Islay C Barne, Jack Barrow, D H Bennett, F A Binks, Andrew Bogdanovitch Claude Brun, J M Burbury, C R K Carroll, D I Chapman, H R Claff, Lionel Cohen, Brenda Collar, C W Coplans J A B Cotsell, W R Cyrlas Williams J H Dadds, E B Dawe Joseph Denfield G D Denlow, A G Doughty, C E Drew Margaret D D Dudley Brown, C T F Ealand, W K Earle, H H G Eastcott, Christine Ecroyd, E M Ensor, E G Essery Joan Fitzherbert B J Fowler, A J Fraser Simson, S M Frazer, Franz Freund, P D Gange, O F Garai, Leo Garland Collins, A J Gaskell, J E Gilbert R A Gill, B M Girgis Gerald Godfrey, A H F Gow, C N Grainger, J C Gray, J L Greaves, Barbara J Greenwood, C H Greer, A G Gregory, E W Guillaume J W P Gummer, A W Hagger, F A H Hall, Winefride M Hamilton, G P Hartigan, P L M Hartley, M C Head E H Hemsted, G G Henn Maurice Hershman J H Hicks, A C Higgitt, G de B Hinde, J C Holman Emily M Horsfall E W Hyde N N Iovetz Tereshchenko, J D James, Elizabeth E Johnson, A C V Jones, H W Jones, H P Jones, H O Jones, R D Jordan, H L Joyce Henry Kanter Marie D Kelleher, R E Kelly, E R Keyworth, J H Kirkham S H Kutar, R U F Kynaston, Bernard Lewis, D W Liddell, Isabelle G Little R R H Lovell, N W R Lucas, Silvia C Lucas, W C Lyon G E McFall, W E Mahon, Jankinath Manhas F R C Manning, L W C Massey, T R Maurice, Joyce B M Mayes F B Meade V C Medvei, Joan S Millett, A F Mohun, R A R Montgomery J V Morris, Madeleine B Morris, J H M Munro, Smarn Muntarbhorn, T A Narayanan L P A Newborne, D J O Brien, William O'Brien, C B O'Carroll, E E Oddie F H Packer, R H A Parker, C N Partington A J Patenall G H Pearson Rosa M Piggot, Louis Portelli, F T G Prunty, S D Purcell, Harold Reeback, H N Reed, P A Rees R L Rees, R E Renaud, G K C Rettie, R E Rewell, Florence C R Richardson Kathleen P Richardson, M J Riddell E F Ridley, Ronald Robins Browne, G K T Roche, J A J Sandilands, Witold Schey Isabel B Schooling, C M Shafto, R G Sheppard, J C Smith, R J Stanley, R B Stark, Tobias Sternberg, J N Stirling H A W Stormont, R J Stout, F G Strong, P N Swift, J M Swithinbank M R Thompson, D N Thornton, Robert Tilley, St J M A Tolhurst Samuel Tomback, Eileen D Trafford, Ruth D Usher, P C van der Westhuizen, A S Veeder, T H E Verdon G B R Walker, F J H Walters, W R Watson, S D V Weller, B W Wells Moyr Welply Hermon Whittaker R D Wilkins, R J G Williams A R H Williamson, J B Wyman

Diplomas were granted jointly with the Royal College o Surgeons, to the following candidates —

D P H —G P Charles Gwendoline M Edwards, Joan M Faulkner, Samuel Leff, I B Sen Gupta

D M R —Benjamin Jolles, J H Wilding

Diplomas in anæsthetics and in laryngology and otolog were also granted to the candidates named in the report of th meeting of the Royal College of Surgeons in our issue of Dec 21, and in psychological medicine to those named in our issu of Jan 18

University of London

At recent examinations the following were successful —

DIPLOMA IN CLINICAL PATHOLOGY

A R Aidin, J W Clegg, J T Quinlan, Gaya Prasad, J E Stritch, Frieda Young

University of Oxford

Lord Nuffield has given £25,000 to the university t encourage research in ophthalmology The money is to b used to appoint a research assistant to the Margaret Ogilv reader in ophthalmology

Radium Gift from America

Two centres for the supply of radon are working in th country, but the supply still falls far short of the deman When this was made known to the British War Relief Societ in New York, through its British representative, £5000 wa speedily cabled to London to remedy the deficiency T give effect to the gift at the earliest possible moment th British Hospitals Association approached the Middlese Hospital, which consented to start and administer anoth centre for the supply of radon, and work has already begu on it

Health of the Student

At the annual convention of the Scottish National Unic of Students in Aberdeen the recommendation of its medic office to set up a student health insurance scheme wa adopted The medical office urged the establishment routine medical inspection for students and the formation a small medical panel in university towns Younger teache whose interest in students' welfare was known would compo the panel of advisors, and students could choose their ow doctor by registering with the local students' representati council and paying a fee of 10*s* or £1 Dr J H F Brothe ston, director of the medical office, said that already medic inspection at certain of the universities had found man unsuspected cases of tuberculosis and one or two of diabet and nephritis

---

Since the publication of the last list of subscriptions to th Medical War Relief Fund, £1700 has been received, bringin the total to over £16,000

Colonel Walter Elliot, sometime Minister of Health, ha been appointed director of public relations at the War Office i succession to Major General J H Beith

A meeting of the Paddington Medical Society will be hel at 3 P M on Tuesday, Feb 11, at the new tuberculos dispensary, 14, Newton Road, W 2, when Dr Alexand Baldie will open a discussion on the medical aspect of civili morale and crime in war time

In recent casualties lists the following deaths are announce Major J S McMillan, I M S , Captain G C Retz, M B Dub I M S , Lieutenant F C McLaren, M B Glas , R A M It is also announced that Probationary Temp Surge Lieutenant C L Pretre, M R C S , R N V R , of H M *Acheron* is missing, presumed killed

The Minister of Labour and National Service remin employers that the regulations prescribing standards lighting in certain factories came into force on Feb 1 T new regulations (see THE LANCET, 1940, 2, 573) are based the fifth report of the Departmental Committee on Lightin in Factories

In view of the number of nursing matters which co under the control of the Ministry of Health in war time, a to prepare for postwar developments, the Royal College urging the Minister of Health to establish a division nursing within the ministry, which would be administer and staffed by suitably trained and experienced nurses

DEVELOPMENT OF PROVINCIAL MEDICAL EDUCATION ILLUSTRATED IN THE LIFE AND WORK OF

CHARLES WHITE OF MANCHESTER *

By Arthur H Burgess, MB MSc Manc, LLD, FRCS, FACS

CONSULTING SURGEON, MANCHESTER ROYAL INFIRMARY AND CHRISTIE HOSPITAL, PROFESSOR EMERITUS OF CLINICAL SURGERY IN THE UNIVERSITY OF MANCHESTER

On scrutinising the list of my 80 predecessors I find that I am the first Hunterian orator who is an entirely provincial surgeon—one who has neither received his surgical education in London nor practised his profession there, one as yet untainted with metropolitanism I mention the fact to excuse my action in departing from the custom of making John Hunter the main theme of discourse, today is a provincial's day out, and I am taking as my text the life and work of Hunter's famous contemporary provincial surgeon Charles White of Manchester born in the same year as John Hunter, his fellow-student and life long friend

Charles White, born at Manchester on Oct 4, 1728 was the only son of Dr Thomas White who practised there at King Street, and who had not only acquired a great reputation for skill in midwifery but was actually the first in England to perform cæsarean section Young White received his general education privately, but while little more than a boy he was allowed to assist his father with midwifery cases At the age of twenty, he was sent to London and joined, at the same time as John Hunter, the school of anatomy of William Hunter, John's elder brother He afterwards spent a winter at Edinburgh and rejoined his father in 1751 He agitated so actively for the establishment of an infirmary for Manchester that a prominent local merchant Joseph Bancroft, impressed by White's skill and energy, offered to defray all expenses of an infirmary for one year if he would give his professional services thereat A house was taken—No 10, Garden Street, Shudehill—and on June 24, 1752, was opened with 12 beds This proved so successful that larger premises were soon required and on April 9, 1755, the new Manchester Public Infirmary was opened with 40 beds and a medical staff of 3 physicians and 3 surgeons The infirmary remained on the same site until 1908 when it was removed to its present premises with 649 beds, and an honorary medical staff of 44

Charles White from an engraving

White married, in 1757, Ann, daughter of John Bradshaw of Bradshaw Hall, Shudehill, by whom he had four sons and four daughters Two sons entered the medical profession and assisted their father for a time, but all four predeceased him In 1762 he was elected a fellow of the Royal Society—five years before John and nearly six years before William Hunter received this honour On the same day he received the grand diploma of the Company of Surgeons the body which in 1800 became the Royal College of Surgeons in London and in 1843 the Royal College of Surgeons of England He was one of the founders of the Manchester Literary and Philosophical Society which still flourishes † and for 23 years was its vice-president

Owing to a disagreement with the board of management in 1790 Charles White, after 38 years' service, resigned from the staff of the infirmary along with the rest of his colleagues In the same year he and his son Thomas and two other colleagues founded the Manchester Lying-in Charity, precursor of the present combined St Mary's Hospitals of the city, and he served on its staff for 21 years under the singular title of "man midwife extraordinary" To it he presented his museum of pathological specimens which was unfortunately destroyed by fire in 1847

Sale Priory

White's father in his later years had retired from practice to live at Sale Priory, about six miles from Manchester, and on his death there in 1776 this came into the possession of Charles White who used it as a country residence In 1803 he contracted ophthalmia which destroyed the sight of his left eye Nevertheless he continued to practise and even to operate until a similar attack in 1812 left him totally blind He then retired to Sale Priory where he died on Feb 20, 1813, at the age of 84, and was buried in Ashton-on-Mersey church

WHITE ON PUERPERAL FEVER

White's magnum opus was his "Treatise on the management of Pregnant and Lying-in Women," first published in 1773 He dedicated it to his first medical teacher, Dr William Hunter, then physician extraordinary to Queen Charlotte, "as a small acknowledgment of gratitude for the advantages I received in my education from your instructions, and the kind offices of a friendship with which you have ever since honoured me" The treatise embodied the experience of 27 years of midwifery practice, an experience which had profoundly impressed him with the methods then in vogue Midwifery was almost exclusively confined to ignorant women whose imperfect knowledge of their art had been handed down orally from their predecessors, medical men were called only in cases presenting unusual difficulty White described the prevailing practice in these words

> When the woman is in labour she is often attended by a number of her friends in a small room, with a large fire, which, together with her own pains, throw her into profuse sweats, by the heat of the chamber, and the breath of so many people, the whole air is rendered foul and unfit for respiration . . If the woman's pains are not strong enough, her friends are generally pouring into her large quantities of strong liquors, mixed with warm water, and if her pains are very strong, the same kind of remedy is made use of to support her As soon

---

* The Hunterian Oration for 1941 delivered before the Royal College of Surgeons of England on Feb 13

† Since these lines were written the house of the society has been completely destroyed in the Manchester blitz

in procuring me an introduction to Robert Brown. I wanted to examine the entozoon with a microscope, and there was none in the hospital. I thought I might get help from Mr Children, who was then chief of the Natural History Department of the British Museum, and to whom Mr Dawson Turner had given me a letter of introduction. He, however, had no microscope, but suggested that "Robert Brown might help me." So we went at once to the little room in the Museum in which the great botanist was at work among books and specimens, and I remember Mr Children's first question, "Brown, do you know anything about parasitic worms?" and the answer, "No, thank God." But he let me look at my specimens with his little single microscope—the same, I think, that he had done his own grand work with; and I made the sketches of them with which to illustrate the paper read at the Abernethian Society. This, Paget concludes, was certainly the first account given of the new entozoon; but Owen, to whom specimens were taken when I had seen that there was a "worm," read a paper on it at the Zoological Society, and gave it its name. It mattered little; the repute of the discovery would have been of no great use to me, and I should have gained less happiness by disputing it and obtaining it than I have enjoyed in the personal friendship with Owen ever since.

A STANDARD WHOLEMEAL LOAF

THE reinforced flour, with added vitamin B_1 and calcium, is not likely to be on sale for several months, and in the meantime the Ministry of Food are introducing a standard "wholemeal" flour of 85% extraction. It is hoped that this flour will be available almost immediately. The price of the new loaf will be kept the same as that of the present white loaf (8*d* a quartern) by a Government subsidy, and though its adoption will not be compulsory it will no doubt largely take the place of the white loaf. An extraction of 85% of the wheat berry is about the maximum practicable—only certain gritty parts of the bran will have been removed—and the rise from the present 73% extraction of white flour will have repercussions on the alimentary system of at least a few consumers. In the vast constipated majority the change should be for the better, and the relaxed few will still be able to get their white bread.

MEDICAL PRACTICE IN RUSSIA

PROBABLY only those unaware of present trends of thought would have been surprised to find the rooms of the Medical Society of London filled to overflowing during a severe daylight air-raid by people eager to hear of the modern developments of medicine in the U S S R. The meeting was organised by the Society for Cultural Relations with the U S S R and was presided over by Mr Somerville Hastings. The discussion was opened by Prof Wood Jones who had had recent experience of refuge centres. His suggestion that reform of medical practice must be an inevitable sequel to those changes in the structure of society that are destined to come about gained rather than lost in cogency by the recent havoc that every member of the audience must have witnessed on his way to the meeting. Dr Lipetz, who had first-hand experience of medical practice in the U S S R, said that the general practitioner there is in no way better equipped to deal with sick humanity than his counterpart in England, but that the conditions under which he works—the absence of hurry, the constant presence of colleagues in the clinics, and the general atmosphere prevailing in them—make him more efficient in preserving national health. Dr Joan McMichael dealt with public health and the prophylactic approach in the U S S R; to many, her facts and statistics were new and surprising. Antenatal care, infant welfare, the rehabilitation of the sick, the whole machinery for ensuring the prevention of disease, made a utopian but documented story. She reverted to a remark of Prof Wood Jones that man was a captive animal for whom captivity had added to, rather than subtracted from, a constant load of fears and anxieties; and she pictured a state of life, well on its way to attainment in Russia, in which the constant anxiety of sickness and all that it means to the wage earner is largely eliminated. Many must have carried from the meeting a wish that medicine here could be practised among a people safeguarded fro cradle to grave by organised preventive medicine.

Droitwich medical committee have asked us to state th reports that it is not possible to get treatment at the spa a incorrect. But accommodation is limited and should engaged well in advance. The St Andrew's brine baths a open and so are the rheumatism hospitals and hostel. I formation can be had from the local spa association.

The Index and title-page to Vol II, 1940, which w completed with the issue of Dec 28, will be ready shortl A copy will be sent gratis to subscribers on receipt a post card addressed to the Manager of THE LANCE 7, Adam Street, Adelphi, W C 2. Subscribers wl have not already indicated their desire to recei indexes regularly as published should do so now.

conducted autopsies on all their fatal cases In 1847 a colleague of Klein's who had been accidentally pricked while making a medicolegal autopsy died of blood-poisoning, and Semmelweis, who attended the post-mortem upon him, was struck by the identity of the appearances disclosed with those in death from puerperal fever He thereupon concluded that the latter must be caused by the conveyance of cadaveric material, adhering to the hands of the students, to the lying-in woman during vaginal examination Consequently, he instructed all students attending the first division to avoid contact with any cadaveric material prior to their daily attendance to scrub their hands thoroughly with soap and water and to soak them in a solution of chlorine before and after every examination of a patient. This practice resulted in a fall of the death-rate of the first division from 11 4% during 1846 to 1 28% in 1848 Semmelweis then promulgated the doctrine that puerperal fever is caused by the conveyance to the lying-in woman of particles of cadaveric material through the agency of the examining finger At that date he apparently considered this the only cause and took none of the precautions adopted by British obstetricians since the time of White In 1847, however two consecutive outbreaks of puerperal fever were traced to the handling of foul discharges from two patients with a cancer of the cervix and a suppurating knee respectively. Semmelweis thereupon added the doctrine that puerperal fever might be conveyed by putrid particles derived from living persons, either on the examining finger or through air fouled with their emanations Disgusted with the opposition of his chief, Professor Klein, and others of his colleagues, he left Vienna in 1851 o return to his native city of Buda-Pest, and it was not ntil 1856, after he had been appointed professor of idwifery there, that he came to appreciate the importnce of clean linen and clean dressings He noticed that he sheets "actually stank" with decomposed blood nd lochia In 1857–58 of 449 confinements 18 died of uerperal fever, and early in 1858 10 died thereof in a ingle day, although throughout this period chlorine lisinfection of the examining hand was scrupulously nforced Because of these experiences Semmelweis in 861 added to his previous declarations the statement hat puerperal fever may be conveyed to the lying-in voman by foul bed-clothes dressings and sponges, and by the hands of midwives and nurses He later stated that a puerperal woman may infect herself owing to the retention within the birth-tract of material which has undergone decomposition, that instrumental injuries of the genital passages may produce puerperal fever by self-infection, that free ventilation of lying-in wards is necessary to carry away exhalations from patients, and that an infected puerpera should be promptly isolated

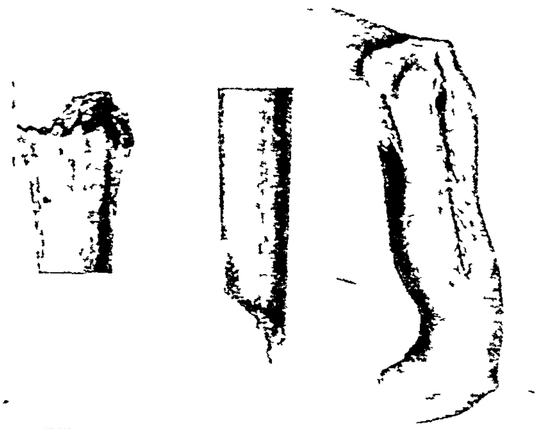
Thus by successive stages spread over several years Semmelweis at last arrived at the identical views and practice advocated by Charles White over 75 years previously The only factor not specifically mentioned by White, and to which Semmelweis had some claim to originality, was the fatal role played by the examining finger fouled by contact with decomposing cadaveric material In White's day Manchester had no medical school and, therefore, no medical students to handle and convey cadaveric particles to the lying-in woman. The claim made by continental writers that our knowledge of the prevention and treatment of puerperal sepsis originated with Semmelweis ignores the whole of the pioneer labours of White and of British obstetricians—work carried out long before Semmelweis's birth All honour to Semmelweis for his courageous advocacy, in face of strong opposition, of measures to diminish the appalling risks of childbirth in his day, but the glory of the pioneer must be awarded to Charles White

PHLEGMASIA ALBA DOLENS

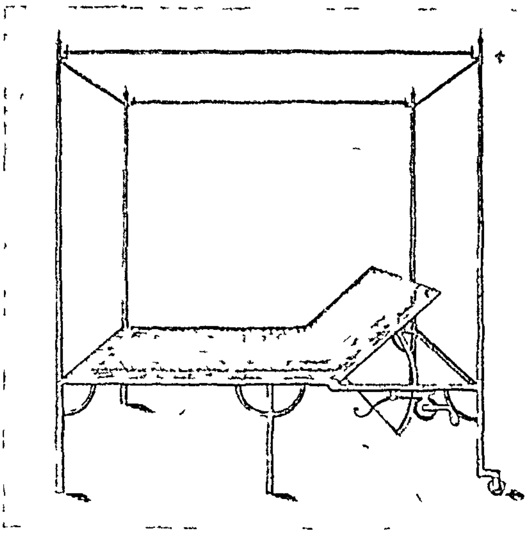
In 1784 White published "An Inquiry into the nature and cause of that swelling in one or both of the lower extremities which sometimes happens to lying-in women," but gave no title to this condition either then or in a second edition which appeared in 1792 Dr John Hull (1800) gave to it the name phlegmatia dolens White, in 1801, enlarged this title into phlegmasia alba dolens puerperarum He described fully its symptoms, course and treatment, and expressed an original opinion of its pathology, attributing it to an obstruction of the lymphatic trunks where they enter the pelvis under Poupart's ligament White considered that compression by the fœtal head of some of the main lymphatic trunks led to their rupture as they passed over the pubic portion of the pelvic brim, and that the cicatrisation following healing of the ruptured lymphatics resulted in their obstruction with consequent swelling of the limb below until such time as an effective collateral circulation became established for this weeks and sometimes months were requisite but, once developed, such a lymphatic by-pass must necessarily prevent a repetition of the trouble in the same limb.

WHITE AS A SURGEON

Not only was White a pioneer in certain aspects of midwifery, but he was also a most original surgeon, and read many papers on surgical topics before the Royal Society From the historical outlook, the most interesting of these and one for which he has since been referred to frequently but erroneously as the first surgeon to excise the shoulder-joint for disease, concerned a boy of 14, of scrofulous habit who was admitted to the Manchester Infirmary in 1768 (White 1770a) A fortnight previously he had been seized with acute inflammation in the left shoulder culminating in a large abscess which had been incised on the inner side of the arm shortly before admission Through this opening the upper end of the humerus was felt to be quite bare and from it escaped a profuse and offensive discharge Though the usual practice for such a condition at that time was amputation White, eight days after admission, exposed the bared portion of the humerus through an external incision , pushing the elbow strongly upwards, he forced the upper part of the bone completely out of the wound and sawed off two inches with an ordinary amputating saw The discharge rapidly diminished, swelling of the limb abated, all hectic symptoms subsided After two months a large sequestrum was removed and the wound healed rapidly, the ultimate result being that, although over four inches of the shaft had been lost either through removal at operation or by subsequent sequestration, yet the arm was but one inch shorter than its fellow, and all movements of the shoulder were completely restored This result exceeded White's most sanguine expectations , believing, as he did, that he had excised the head of the humerus together with the upper part of the shaft, he was astounded at the extent to which the shaft, head, articular cartilage and capsule of the shoulder-joint had apparently regenerated and at the absence of ankylosis after such a severe suppuration This favourable ending is adequately explained, however, on examination of the plate accompanying White's paper, together with the clinical history The bone removed at the operation was obviously the pyramidal upper end of the diaphysis, having no sign of the tuberosities upon it The case, therefore, must have been one of acute osteomyelitis commencing in the upper humeral metaphysis, followed by subperiosteal abscess and later by spontaneous separation at the upper epiphyseal line, the epiphysis



White's case of inflammation of the shoulder as she is delivered, if she is a person in affluent circumstances she is covered up close in bed with additional clothes, the curtains are drawn round the bed and pinned together, every crevice in the windows and door is stopped close, not excepting even the key-hole, the windows are guarded not only with shutters and curtains but even with blankets, the more effectually to exclude the fresh air, and the good woman is not suffered to put her arm or even her nose out of bed, for fear of catching cold She is confined to a horizontal position for many days together, whereby both the stools and the lochia are prevented from having a free exit The lochia, stagnating in the womb and in the folds of the vagina, soon grow putrid Amongst the poor people who live in cellars and upon clay ground floors, the air is made still worse by the dampness and closeness of their houses, the want of clean linen and of cleanliness in general nor is it to be wondered at that they are still in a worse situation in hospitals, where a number are crowded not only in one house but in one ward, where the disease is conveyed from one to another by the putrid miasmata lodging in the curtains, bed clothes and furniture



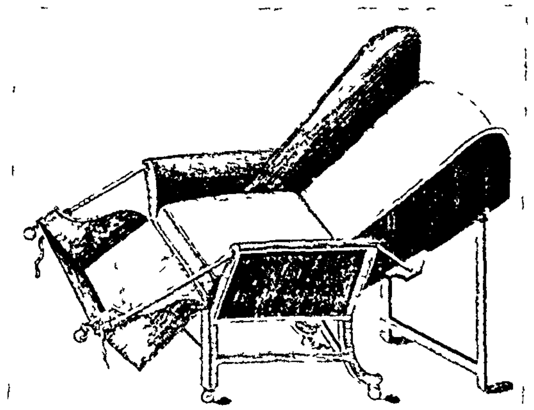
White's bed for the puerperium

Puerperal fever was rife, and the mortality disquieting White urged that special attention be devoted to all such matters as good hygienic surroundings, scrupulous cleanliness both personal on the part of all attendants and also of any material likely to come in contact with the patient —bed-linen, towels, sponges, instruments—proper ventilation of the lying-in chamber, maintenance of an even and moderate room-temperature so as to avoid either chill or over-heating, and correct posture of the patient after delivery In hospitals

If separate apartments cannot be allowed to every patient, at least as soon as the fever has seized one she ought immediately to be moved into another room not only for her immediate safety, but that of the other patients, or it would be still better if every woman were delivered in a separate ward and were to remain there a week or ten days until all danger of this fever is over Whenever a patient has recovered from this fever and is removed to another room the bedding and curtains should be washed, the floor and woodwork cleansed with vinegar, and it would still add to the salubrity of the apartment if it were stoved with brimstone

The posture of the patient after delivery was considered by White of great importance, and in his treatise he figured a chair and a bed which he employed, both designed to allow at will of variations in the angle at which the patient is raised from the horizontal Surgeons will at once recognise this position prescribed by White as identical with that advocated over 100 years later by Fowler, an American surgeon, in the treatment of peritonitis, the object of both White and Fowler being to obtain gravitational drainage It is refreshing to note that in his system of obstetrics and gynæcology A H Curtis (1933), of Chicago, accords the credit to White White advocated getting the patient out of bed soon after delivery—on the same day, if possible, and certainly not later than the second or third day As the result of his methods he reported that of the large number of lying-in patients he had delivered he had never lost one from puerperal fever, and of the few cases developing this complication from non observance of the rules laid down no life had been seriously endangered, nor had any case ended in madness or other disagreeable complaint He, however, qualified this statement as referable only to patients he had himself attended during the time of delivery, and excluded both those to whom he had been called in consultation after puerperal fever had already developed, and also those requiring the use of instruments Successful results of White's methods were also reported by Eli Cope—a former pupil—Professor Young of Edinburgh, Robert Collins of the Rotunda and others Sad to relate, however, a quarter of a century after White's death a serious fall from grace occurred both in the British school and on the Continent largely owing to French teaching The methods of White and his followers were abandoned and puerperal fever again became prevalent even in the Manchester Lying-in Hospital which White himself had founded Nor were matters any better in America when in 1843 Dr Oliver Wendell Holmes used his literary genius to direct public attention to this grave situation

In Vienna in 1789 there had been appointed a professor of midwifery who had studied White's methods in England, and who, in spite of strong opposition, had introduced them into the Vienna lying-in hospital—Professor Boer He held office for thirty years, during which 65,000 patients passed through the hospital with an average annual mortality from all causes of only 1 3% Boer's enemies succeeded in deposing him in 1822 on the pretext of insubordination because he refused to teach midwifery on the female cadaver instead of the leather phantom His successor Klein discarded the English methods and also taught upon the cadaver the mortality rose from 1 3 to 7 8% in his first year and remained high, in some months reaching even 29 3% From 1840 onwards the obstetric work was carried out in two divisions, the first reserved for the instruction of medical students, the second for that of midwives The students were encouraged to make frequent examinations of the patients before, during and after confinement, and practical instruction was given upon the female cadaver Moreover, the students often proceeded from the dissecting or the post-mortem room direct to the lying in room after a very perfunctory washing of their hands In the second division the midwives made just as frequent examinations, but their practical instruction was given on the leather phantom instead of the dead body, nor did they attend either dissections or post-mortems For the six years, 1841 to 1846, the average mortality in the first division was three times, and in 1846 four times that in the second division This appalling difference excited such notoriety and alarm that many women refused to enter the first division



White s chair for the puerperium

THE WORK OF SEMMELWEIS

Ignaz Philipp Semmelweis, who was then assistant to Professor Klein, had charge of the first division and most teachers of anatomy, Jordan had to rely upon the "resurrectionists", this becoming known an infuriated mob on one occasion broke all his windows and kept him prisoner in his own premises for several days Similar scandals in connexion with other anatomical schools and particularly the notorious murders by Burke and Hare in Edinburgh in 1827–28 and by Bishop and Williams in London in 1831, focused public attention upon the question of medical education A select committee of the House of Commons was appointed in 1828 to inquire into the provision of bodies for dissection in the schools of anatomy, and the removal of impediments to the cultivation of anatomical science, upon its report was founded the Anatomy Act of 1832, permitting the unclaimed bodies of persons dying in workhouses to be used for dissection

Jordan's school was closed in 1834, when its students and most of the contents of its museum were transferred to a school in Pine Street opened by Thomas Turner in 1824 This was the first complete school of medicine to be established in the provinces and, in recognition of this, it was granted the Royal patronage After absorbing two other rival schools, it was incorporated in 1872 with the Owens College In 1880 the Owens College became the first constituent college of the Victoria University, though the power to grant degrees in medicine and surgery was not obtained until 1883 and then only in the face of strong opposition from the Royal College of Surgeons and generally from the London medical schools

A not unnatural outcome of the advent of the provincial medical schools was a request that their certificates of attendance should be recognised by the licensing authorities in London and elsewhere So far as Manchester was concerned the Society of Apothecaries had already recognised the certificates of Jordan's school in 1817, of Turner's school in 1826 and of the Manchester Royal Infirmary in 1834, and so had the Royal College of Physicians In spite of repeated requests, however, such recognition was refused by the Royal College of Surgeons which in 1821 had issued a regulation requiring all candidates for its diploma to spend at least six months in study and dissections in the medical schools of London or of the universities of Dublin, Edinburgh, Glasgow or Aberdeen In 1823 another by-law refused recognition of dissections made in the summer months—a blow obviously aimed at the London private anatomical schools where instruction was usually continuous throughout the year so as to minimise the time and expense to the provincial student of the requisite period of study in London In 1824 a further by-law enacted that "certificates of attendance at lectures in anatomy, physiology, the theory and practice of surgery, and of the performance of dissections be not received by the Court of Examiners except from the appointed professors of anatomy and surgery in the universities of Dublin, Edinburgh, Glasgow and Aberdeen, or from persons teaching in a school acknowledged by the medical establishment of one of the recognised hospitals, or from persons being physicians or surgeons to any of these hospitals Guy's, St Thomas's, St Bartholomew's and the London" Thomas Wakley, founder and editor of THE LANCET, pointed out that the tendency of these two regulations was to direct all the fees which might accrue from the teaching of anatomy in England and Wales into the pockets of the London hospital surgeons he considered it not a little singular that of the ten members of the court of examiners by whom these by-laws were enacted at least seven were practising London hospital surgeons

The secretary of the Society of Apothecaries, however, in his evidence before the select committee, stated that "no young men came before the Court of the Society of Apothecaries better qualified in every respect than those who had been entirely educated at Manchester, where excellent lectures on every branch of medicine are given by very competent teachers and the Manchester Infirmary affords, under the physicians belonging to it, most ample opportunities for the acquirement of practical knowledge" Doubtless as a result of this inquiry the Royal College of Surgeons, in August, 1829, issued a regulation allowing certificates of instruction to be accepted "from the several towns in England possessing properly constituted hospitals together with such means and opportunities of teaching anatomy, physiology and surgery by lectures, demonstrations and dissections as shall be approved by the Court of Examiners" The compulsory six months' attendance at one of the London or other recognised schools in Ireland or Scotland was thus finally abolished and the right of the provincial schools to teach anatomy and physiology officially recognised

The results of the examinations in anatomy at the Royal College of Surgeons for a period of three years closely following upon this new regulation of August, 1829, displayed the provincial schools in a very favourable light as compared with those in London, their failures amounting to only 1 7% of total entries as compared with 7 8% of failures among London students

The struggle for the full recognition by the Royal College of Surgeons of clinical teaching at provincial hospitals continued In 1830 the Manchester Infirmary, with 360 beds, applied, with success, for the Royal patronage, and in the hope that this manifestation of Royal approval might influence the Royal College favourably the Manchester Royal Infirmary, as it had now become, on two occasions besought that body to place it upon the same footing with regard to certificates of attendance at clinical teaching as the recognised hospitals in London, Scotland and Ireland—but all in vain The chief provincial schools then petitioned Parliament, and in 1834 a select committee was appointed at which the opposition of the Royal College was voiced by its president, Mr G J Guthrie, and seven members of its council Sir Astley Cooper stated that "Country schools were at a loss in teaching principles, at practice they taught a good deal Students in London acquired a degree of information which was absolutely impossible to acquire from country teachers He knew members of the Manchester Hospital school and thought that a shorter residence in London would suffice for one who had been through it He did not believe that anything like perfection could be obtained anywhere but in London or in some very large town as Edinburgh, Dublin etc" Sir Anthony Carlisle, one of the surgeons at Westminster Hospital (which then possessed only 82 beds) said "Many of the general practitioners of the country have contributed to the improvement of surgery, as, for example, Mr White of Manchester and others, but if Mr White (or the others) had lived in London, I think the collision of metropolitan society would have made each of them greater men than they were—all great men in large states have been resident in the metropolis and, perhaps, have been raised to high eminence by that excitement"

Thomas Wakley, who strongly supported the claim of the provincial hospitals, had already indicated to the select committee on Anatomy of 1828 the absurdity of the position that the Royal College of Surgeons should accept one year's attendance at the Westminster Hospital with only 82 beds and yet required four years at provincial hospitals some of which possessed upwards of 300 beds He hinted that this might not be altogether unconnected with the fact that two of the four surgeons to the Westminster Hospital were on the court of examiners of the Royal College and all four were on the council by which the examiners are elected

Evidence favourable to the provincial schools was given by Mr J Somerville, inspector under the Anatomy Act, who said "Manchester, Birmingham, Liverpool and Bristol have opportunities of teaching anatomy that are not surpassed in any place or town," and by the secretary to the Society of Apothecaries who expressed the opinion that "Students from the country in general were quite as well instructed as those who study only in the schools of London and many evinced a very great deal of information indeed" Owing to a change in the Government following closely upon its sittings, the select committee never issued a report but published merely the evidence given before it The Royal College of Surgeons declined to give way until 1839 when it was finally agreed to accept certificates of attendance on the practice of surgery at any recognised hospital in the United Kingdom Thus was won the protracted fight for the full recognition of the provincial medical schools

Looking back upon this rather bitter controversy of just over a century ago one is left with the impression that the members of the College council of that period displayed an undue regard to self-interest, a narrowness of vision and a lack of foresight happily quite foreign to itself remaining in situ. The synovial cavity of the shoulder escaped serious inflammation owing to the extra-articular situation of the epiphyseal line, and so complete restoration of movement of the joint was not only possible but actually occurred. Thus, although White was not the first to excise the head of the humerus for disease yet, quite unwittingly, he really was the pioneer in the operation of partial diaphysectomy for acute osteomyelitis.

In 1762 White published in London a volume on the "topical application of the sponge in hæmorrhage," based on two communications to the Royal Society. The customary method of arresting hæmorrhage was then by the ligature, which, though successful as a primary application in amputations and other wounds, was said to be the most painful part of the operation since some of the soft parts were usually included within the ligature. Moreover, it frequently failed in lacerated and contused parts and in cases of what we now call secondary hæmorrhage, where the suppurating and softened tissues would not again bear ligation. White advocated the application to the bleeding point of a suitably sized piece of compact and thoroughly dried sponge maintained in place by the firm pressure of a bandage, or by strapping. In his communication to the Royal Society 13 cases were recorded where the use of the sponge had successfully arrested hæmorrhage when all other means had failed, and in his book he stated that he used it constantly, even for the larger arteries, without it ever having failed him. In 1770 he published a further series of successful cases (White 1770b), and he then noted that those parts of the wound to which the sponge had been applied were much cleaner than the rest. This led him to use dried sponge as a dressing to foul ulcers and abscesses, and he found that this cleansed them more quickly and effectually than any other method then known. He gradually developed the practice of leaving the sponge dressings undisturbed until they became definitely offensive, sometimes even for 10 to 14 days, and he would thus seem to have anticipated by over a century and a half the principle of the modern Winnett-Orr treatment of acute osteomyelitis.

White devised a method for reduction of dislocations of the humerus. An iron ring was screwed into a beam of the ceiling and one end of a pulley fixed to it, the other being fastened by bandages to the patient's forearm just above the wrist. The patient was then drawn upwards by the pulley until the whole of his body was suspended by the dislocated arm when, by direct pressure upon the head of the humerus it was usually readily pushed into its socket. To avoid too strong traction upon the forearm and wrist two persons were employed to support these. If a pulley were not at hand, three or four strong men, standing upon a table, lifted the patient by traction upon the arm held erect until his feet were clear of the floor, while the surgeon manipulated the dislocated humeral head. During twenty years he had not failed in any recent dislocation, though he had met with three old-standing dislocations which resisted all methods and remained unreduced.

White (1770c) obtained an interesting specimen post mortem from a female who died in the Manchester Lunatic Hospital in 1768, and who, fourteen years before, had undergone an operation for arteriovenous aneurysm following injury to the brachial artery during venesection. He presented it to John Hunter who placed it in his museum. It shows that three inches of the main artery were obliterated as the result of its ligation above and below the aneurysm, and that a very remarkable collateral circulation had developed.

Stone in the bladder was then common in Yorkshire, and White soon acquired a great reputation as a lithotomist. A large vesical calculus was one of the very few specimens saved from the fire which destroyed his museum; it was removed by him by lateral lithotomy. White's surgical contributions generally show a strongly conservative tendency, and he has, indeed, been acclaimed as the "Father of conservative surgery."

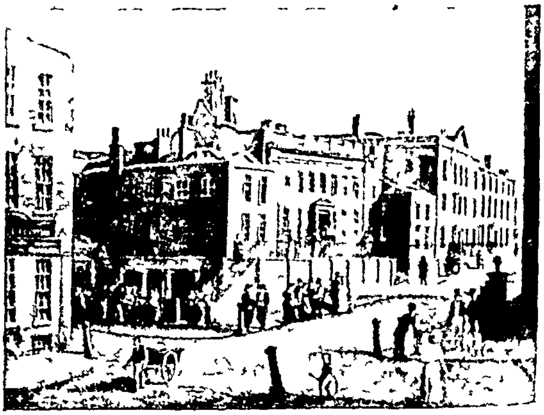
A STUDY IN EVOLUTION

Doubtless influenced by his early association with John Hunter he was always interested in natural history; of many papers read to the Manchester Literary and Philosophical Society the most important was a series on "The regular gradation in man and in different animals and vegetables, and from the former to the latter." They were published in book form in 1799. The idea was suggested to him when present at a lecture by John Hunter illustrated by a number of skulls which Hunter placed on the table in a regular series ranging from the human skull, with its varieties in the European, the Asiatic, the American and the African, downwards through that of the monkey and ultimately to the dog "in order to demonstrate the gradation both in the skulls and in the jaws." Stimulated by this lecture White, for some years, spent his scanty leisure in collecting and reflecting upon an enormous number of biological facts to prove the existence of gradation as a general principle running throughout nature. This might suggest that he had some inkling of the hypothesis of evolution, but he disbelieved in any progressive variation in species, considering that all species were unchangeable and retained the features which characterised them at the time of their creation. He stopped short of the logical conclusion, possibly because of his strong religious convictions.

In the course of these investigations he made measurements of the head and limbs of a large number of negroes among the sailors visiting the port of Liverpool. On this account he has been styled the "father of anthropometry," and this he certainly was so far as concerns living persons. Anthropometry, however, includes measurements upon the skeleton as well as the living, and in this aspect he had been preceded by Camper and others. But he was the first to discover that the forearm of the negro as compared with the upper arm is longer than the forearm of the European, and that of the ape longer than that of the negro.

PROVINCIAL MEDICAL EDUCATION

The first course of public medical lectures in Manchester (and probably in England outside London) was delivered in 1783 at the house of the Manchester Literary and Philosophical Society by Charles White and his son Thomas, and was open to the lay public as well as to medical men. They also started in 1787 at their own house in King Street the first instructional class confined to medical students, with lectures on anatomy and physiology.



Charles White's house in King Street where classes for medical students were first held in Manchester

In the early part of the nineteenth century those desirous of obtaining a medical qualification were obliged to attend hospital practice in London in order to become eligible for admission to the examinations for the licentiateship of the Society of Apothecaries or the membership of the Royal College of Surgeons. Only in London, Edinburgh, Glasgow, Aberdeen and Dublin were there any medical schools. In 1814 Joseph Jordan, the "Father of provincial medical education," as he has been justly styled, started a school of anatomy in Bridge Street, Manchester. His lectures quickly became popular and in 1817 were recognised by the Society of Apothecaries as qualifying to sit for their diploma—this being the first recognition of provincial medical instruction by any licensing body in this country. To obtain bodies for dissection was difficult in those days, and like

DISCUSSION

There are several favourable reports on the results of local treatment with the sulphonamide drugs in various types of infected wounds (Jensen, Johnsrud and Nelson 1939, Nitti 1939, Key and Burford 1940, Herrell and Brown 1940) and on experimental gas gangrene (Legroux 1940) Following on Legroux's work, local prophylactic measures with these drugs have been used in both the French and British armies with good results though *in a* certain number of cases gas gangrene did make its appearance in wounds (Handley 1940) Our experimental *results show that these drugs have a definite* bacteriostatic effect on the organisms of gas gangrene, but that it is much less, both in vitro and in vivo, than that against many aerobic bacteria For example, one knows that for a streptococcal infection one requires a sulphanilamide level in the blood of about 5–10 mg per 100 c cm, which is about 3 10^{-4} *M*, the concentration required for inhibition in vitro (Woods 1940) A much higher concentration of these drugs is required to prevent the development of gas gangrene, and there is no more convenient way of attaining this than by applying the drugs in large doses at the site of injection

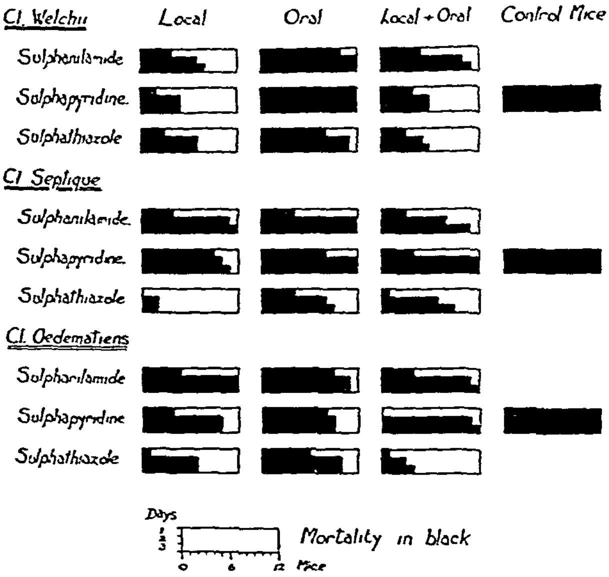

FIG 1—Comparative effect of three sulphonamide drugs on three gas gangrene organisms (see table III)

Regarding the choice of the drug to be used as a prophylactic against the development of gas gangrene in wounds our experiments indicate that the three sulphonamides used are of almost equal value against *Cl welchii* Since sulphanilamide is the cheapest and the most available of all the sulphonamides we would recommend its use in all such cases both for treatment and prophylaxis If the presence of another infecting organism is suspected another drug might be tried We advise that most wounds should be packed with at least 10 g of sulphanilamide, or more if possible If the dose were to correspond to our findings in mice it would be about 50 g, such amounts could hardly be applied to most wounds, so the inference is always to put in as much as possible

TABLE IV—EFFECT OF LOCAL AND REMOTE INTRAMUSCULAR SULPHANILAMIDE ON *CL WELCHII* IN MICE

That the association of Charles White with John Hunter as fellow-students produced a profound and lasting impression is shown by White's insatiable appetite throughout his long life for work of a practical and experimental nature, in his early start as a collector of specimens and founder of a museum, and by his studies in comparative anatomy, in botany, in fossils and in anthropometry Like Hunter, he was an eager and serious student of nature in all her protean manifestations John Hunter's indisputable right to immortal fame rests upon many factors, among others, his unique knowledge of anatomy both human and comparative, his persistent advocacy that " Structure is only the ultimate expression of function " with its consequent linking of anatomy with physiology and of both with pathology and surgery, his emphatic and enthusiastic insistence upon the experimental method of investigation, and, as a crowning glory, the foundation of our superb Hunterian museum, second to none elsewhere John Hunter loved work for work's sake, and although he acquired a lucrative practice yet money to him was of value only in that it supplied the wherewithal to continue his researches and to augment the priceless treasures of his collection His museum, said to have cost him £70,000 in additio years of incessant toil, was his only material pos at death, and, pending its sale to the Governm years later for £15,000, his widow was compelled to the King's Bounty Hunter's life's work calls viv mind those lines of Rudyard Kipling

> " And only the Master shall praise us, and only t
> Master shall blame ,
> And no one shall work for money, and no one sh

CHEMOTHERAPY OF GAS GANGRENE

By James McIntosh, M D , LL D Aberd
PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF LONDON, DIRECTOR OF THE BLAND SUTTON INSTITUTE OF PATHOLOGY, MIDDLESEX HOSPITAL, AND

F R Selbie, M D Aberd
ASSISTANT PATHOLOGIST AT THE INSTITUTE

Experimental and clinical studies have shown that the sulphonamide drugs have a bacteriostatic action on the causal organisms of gas gangrene These studies, at first confined to the effects of oral administration (Domagk 1937, Long and Bliss 1937, Stephenson and Ross 1940, Henderson and Gorer 1940), were extended to the effects of local application of sulphanilamide in infected guineapigs by Legroux (1940) and gave promising results However, the practical application of these findings to war wounds and air-raid casualties does not appear to have given results such as were to be expected from the preliminary experiments The experiments to be described were undertaken with the idea of finding how this discrepancy arose, and to probe further the local application of these drugs to wounds

In the first place, we considered it essential to produce a rapidly fatal intramuscular lesion in mice with *Clostridium welchii*, for this micro-organism is by far the most freqent cause of gas gangrene Because of the difficulty of reproducing regularly a virulent intramuscular infection with *Cl welchii*, much of the previous work on the chemotherapy of gas gangrene in mice has been done on *Cl septique* or on *Cl welchii* after intraperitoneal or intradermal injection However, using a virulent strain of *Cl welchii*, recently isolated from a severe case of gas gangrene, we were able to obtain regularly a mortality of 100% in 24 hours in mice after intramuscular injection along with calcium chloride as recommended by Bullock (Gye) and Cramer (1919) The successful production of this very severe muscular lesion in mice has afforded us a convenient test by which the relative merits of various preventive and therapeutic measures can be readily tested, and has also enabled us to assess the comparative value of three of the sulphonamides against *Cl welchii*, *Cl septique* and *Cl œdematiens*

MATERIAL AND METHODS

Preparation of bacterial suspensions—The strains of clostridia employed were *Cl welchii* B S I strain 186 from a recent case of gas gangrene, *Cl septique* B S I strain 84, and *Cl œdematiens* B S I strain 85 A relatively toxin-free suspension was prepared by centrifuging an 18 hour meat-broth culture and washing twice in saline The sus was then diluted to give an opacity which, in the con of our experiments, would kill all inoculated mice wi hours The opacities usually required for the three org corresponding to standard opacities for *Bacterium col* roughly *Cl welchii* 1000–2000 million , *Cl septique* 1500 million , *Cl œdematiens* 100 million per c cm

Inoculation of mice—The control, or untreated, mi injected in the muscles of the right thigh with 0 2 c equal parts of the bacterial suspension and 5% c chloride

Administration of drug—(*a*) *Local* For local adm tion the drug was ground in a mortar and suspended infecting inoculum so that the required dose of the dr contained in 0 2 c cm The mice were then injecte 0 2 c cm of the suspension in the same manner as the mice (*b*) *Oral* The mice were injected in the same the control mice and were immediately given 25 mg drug in a 10% suspension in 50% mucilage thro œsophageal cannula This dose was repeated at 6, and 48 hours (*c*) *Local and oral* This consiste combination of the local and oral administrations o the oral dose at the time of inoculation

EXPERIMENTAL

The results of our experiments are shown in tab where the effects of the drugs in delaying death estimated from the average number of days survi given in the last column This figure is obtain dividing the total number of whole days survi each group of mice by the number of mice in the (Whitby 1937) The mortality for only 3 days sidered, because mice living beyond this interval survived the immediate effects of the experi disease

TABLE I—EFFECT OF LOCAL SULPHANILAMIDE ON *CL*
IN MICE

Inoculum	Sulphanilamide (mg)	No of mice	No of mice dying on day			Survived three days
			1	2	3	
Culture (subcutaneous)		20	12	5	2	1
	20	20	5	2	1	12
Washed bacterial suspension + calcium chloride (intramuscular)		60	60			0
	20	12	8	1	0	3
	10	48	6	8	1	33

The experiments of table I show that 20 sulphanilamide given locally delayed death consid after subcutaneous injection of cultures of *Cl w* but we decided that the mortality in the control mi not high enough for further experiments We then washed suspension of the organisms injected along a the anus a carcinoma with fleshy overhanging edges d the lumen of the gut for 7 cm Muscularis invaded, ltrated fibrous adhesions fixing gut to posterior wall of dder and left adnexæ Golden yellow cortical adenoma cm in diameter in left adrenal Chronic venous conges- ı of small atrophic liver Very flabby myocardium

entral nervous system—Middle ears, bony and venous ıses clear Gross flattening of cerebral convolutions rked tentorial cone (left 1 cm wide, right 0 6 cm wide) ›tomeninges opaque and thickened over basal cysternæ th lateral ventricles equally and much dilated, containing ıtly turbid fluid, ventricular walls white but patterned h purple dilated veins Both choroid plexuses bound wn by bulky grey semi-translucent sheath of fibrin undant faintly turbid fluid throughout spinal thèca, and its lower end a thin waxy sheet (0 4 × 0 2 cm.) lying free ept for few tenuous adhesions

Microscopically—The outstanding lesion was a fibrino- rulent lateral ventricle choroiditis There was slight rivascular cellular infiltration of the ventricular walls, ıted to the sub ependyma The walls of the third ventricle re involved less There was an adherent pear shaped lypus of fibrin plugging the aqueduct of Sylvius Sections the frontal cortex showed no neuronal damage, but slight ononuclear infiltration of the subarachnoid space There re more abundant swollen macrophages and some fibro- astic proliferation in the cysterna magna The meninges of e cord showed nothing but slight perivenous lymphocytic filtration suggestive of a subsiding infection. Ziehl-eelsen and Gram stains did not show any organisms

Cause of death—Meningitis and fibrino purulent ventri- ulitis following spinal anæsthesia Acute internal hydro- phalus

ÆTIOLOGY

Routine bacteriological examinations of samples of erebrospinal fluid were made throughout the epidemic o organisms were recovered except in a single case in hich three colonies of a small gram-negative bacillus hich fermented no sugars were obtained on an inocu- ated blood-agar plate At the time this organism was hought to be an accidental contaminant and the cultures ere discarded Towards the end of the epidemic Prof Vilson Smith of the bacteriological department, Sheffield Jniversity, was asked to investigate the condition His nvestigations are not yet completed but he has allowed ne to quote the following note

A review of the circumstantial evidence pointed to a cold- water filter as being a possible source of infection This ilter was a Berkefeld multiple candle type and was connected directly to the roof water tanks The outflow water, assumed to be sterile, was used to rinse the lumbar-puncture needles which were kept in formaldehyde vapour The candles were frequently disconnected, scrubbed and boiled as otherwise they soon became blocked Three of the candles had recently been renewed but the other three were old and worn Water from both inflow and outflow pipes was examined bacterio- logically and by animal inoculation with a view to the isolation of a pathogen c virus No evidence of virus contamination was obtained but a small gram negative bacillus fermenting none of the usual sugars was isolated from both inflow and outflow water Attempts to isolate this organism from the cerebrospinal fluid of the only two cases still available were unsuccessful nor could serological evidence be obtained to incriminate it as the cause of the meningitis Animal inocula- tion experiments with these samples of cerebrospinal fluid were carried out in the hope of isolating a virus, these also were unsuccessful It is hoped to publish a full account of this investigation when completed

In view of these findings the use of the filter was promptly discontinued, after which no further cases of meningitis occurred Thus although circumstantial evidence strongly suggests the contaminated water as the source of infection direct proof of this has not been obtained

SUMMARY

In 11 patients out of 96 operated on under spinal anæsthesia in one theatre a low-grade meningitis developed All except one recovered completely. In the one patient who died autopsy showed a fibrino-purulent ventriculitis Circumstantial evidence pointed to a bacterial infection due to the use of a defective filter, but this could not be proved

My thanks are due to Prof Wilson Smith for his help

CULTURE OF INTESTINAL PROTOZOA

By S Adler, M.B Leeds, M R C P
PROFESSOR OF PARASITOLOGY IN THE HEBREW UNIVERSITY OF JERUSALEM, AND

Annie Foner, M R C S
ASSISTANT IN THE DEPARTMENT

With the extension of hostilities to the Middle East and the tropics the cultivation of intestinal protozoa has become of interest to a wider circle of workers, and the following notes on culture methods may prove useful

E HISTOLYTICA AND *TR INTESTINALIS*

During the last two years we have experimented with various media for intestinal protozoa, Boeck and Drbohlav's (1925) Dobell and Laidlaw's (1926) medium, bouillonserum media and a semi-solid medium of the following composition —

Agar (3%)	1 part
Locke (containing 0 1% glucose)	8 parts
Inactivated serum (horse, cow, goat, or human)	1 part

Rice-starch is added, as in Dobell and Laidlaw's medium

The medium is tubed in 5 c cm amounts

The semi-solid medium has several advantages over the usual media for the cultivation of *Entamœba histolytica* For the initial culture we use either fresh fæces containing amœbæ or cysts concentrated by the method of Yorke and Adams (1926), allowed to stand for half an hour in 5% HCl and subsequently washed by centrifuging in saline Although growth on the semi-solid medium is slower in the first few days the ultimate culture is much richer, for the amœbæ grow throughout the whole column and are not confined to the bottom of the tube as in the other media The culture attains its maximum in about 7 days and the life of a culture varies from 10 to 14 days

Even better results are obtained if this semi-solid medium is inoculated with a culture of *Bacillus prodigiosus*, and a day or two later is inoculated either with washed cysts or amœbæ from fresh stools Within 24 hours active amœbæ are found throughout the whole column of the medium and within 48 hours the culture is very rich The average life of a culture is about 7 days, but individual cultures may live up to 17 days The great advantage of this method is that with repeated subcultures the intestinal flora introduced in the initial culture is to a considerable extent modified, and rich cultures can be inoculated intraperitoneally or subcutaneously into laboratory animals without causing peritonitis or sepsis *E histolytica* can be obtained from mixed cultures of *E histolytica* and *E coli* by inoculating them subcutaneously into a rabbit, *E histolytica* is then recovered without *E coli* by culturing from the infected skin on to semi-solid medium plus *B prodigiosus*

A rabbit was inoculated subcutaneously and intra- peritoneally with a mixed culture of *E histolytica* and *E coli* Twelve days later a subcutaneous abscess was found round the site of the inoculation The abscess was opened and pus evacuated The pus contained no amœbæ The wall of the abscess was scraped and found to contain active *E histolytica* which was easily cultured on semi-solid medium + *B prodigiosus*

The advantages of working with a culture of *E histolytica* plus a non-pathogenic bacterium with the object of attempting bacteria-free cultures of *E histolytica* are obvious

The semi-solid medium plus *B prodigiosus* was found very convenient for the cultivation of *Trichomonas intestinalis* Rich cultures throughout the whole column of the medium are obtained within 24 hours and a culture lives up to 15 days

CULTIVATION OF *BALANTIDIUM COLI*

A case of balantidiosis was found in the Mea-Shearim quarter of Jerusalem under circumstances which practically precluded all possibility of contact with pigs Blood, mucus, pus and *Balantidium coli* were abundant in the stool Cultures were attempted on Yarbrough's medium, on Boeck and Drbohlav's medium with starch

TABLE V—EFFECT OF DELAYED LOCAL SULPHANILAMIDE ON *CL WELCHII* IN MICE (DOSE 40 MG)

Sulphanilamide given after hours	No of mice	No of mice dying on day			Sur vived 3 days	Av no of days survived
		1	2	3		
0	6	2	0	0	4	2
1	6	4	0	0	2	1
3	6	5	1		0	0 2
6	6	6			0	0
Controls	6	6			0	0

without interfering with the proper treatment and healing of the wound Although small doses of a few grammes might have some value they would be inadequate as a local application for most wounds, for results show that these smaller doses, even when supplemented by oral treatment, do not prevent the appearance of gas gangrene in certain cases This is apparently due to the rapidity with which these drugs are absorbed from the local area, as is borne out by our experimental observations on the elimination of these drugs in mice (fig 2) Again, in addition to their comparatively weak action on anaerobic bacteria, it is known that there are many products of breaking down tissue which inhibit the bacteriostatic action of these drugs (Fleming 1940)

The greater efficacy of the sulphonamide drugs when they are applied directly at the site of local infections falls in line with the finding of McIntosh and Whitby (1939) that these drugs act directly on bacteria by neutralising some metabolic or enzymic activity, and also with the recent work of Woods (1940) showing that sulphanilamide acts in bacterial cultures by blocking the utilisation of *p*-amino-benzoic acid, an essential metabolite for bacteria That this mechanism is the same in the therapeutic action of sulphanilamide on a streptococcal infection in mice was shown by Selbie (1940), and it therefore appears that the bacteriostatic effect of these drugs on a sensitive organism depends to a large extent on the concentration of the drug in contact with the infecting organism This is an additional reason for the direct application of the sulphonamide drugs to the infected area

Preliminary experiments seem to suggest that antitoxin is less effective than local sulphanilamide in preventing the development of *Cl welchii* infection in mice injected intramuscularly with calcium chloride as an aggressin when the culture is of high virulence A dose of 2 5 units, equivalent to 8000 units in man, saves fewer mice than local sulphanliamide However, small doses of antitoxin prevent the death of mice after the intramuscular injection of cultures of *Cl welchii* without calcium chloride and where the preformed toxin acts as an aggressin But in man at the time of wounding the aggressin would not be preformed toxin, it would be derived from the soil, and this would explain many of the failures of antitoxin to prevent the development of gas gangrene The treatment of an established infection is another problem where antitoxin is of great value in controlling the toxæmia A potent antibacterial serum, on the other hand, might be a useful adjunct to the sulphonamides in treating the initial infection

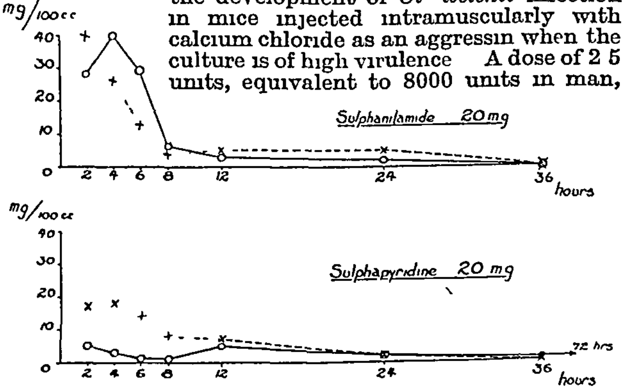

FIG 2—Sulphanilamide and sulphapyridine in blood after administration by mouth (dotted line) and intramuscularly (continuous line) in mice

SUMMARY

A study has been made in mice of the prophylactic value of sulphanilamide, sulphapyridine and sulphathiazole against *Cl welchii*, *Cl septique* and *Cl. œdematiens*

The results show that these drugs are of considerable value in preventing the development of gas gangrene provided they are administered locally, in large quantities and soon after the infection We recommend sulphanilamide as the most suitable prophylactic against anaerobic infections of wounds

All three drugs were found to have much the same value against *B welchii* infections, with sulphapyridine slightly the most effective Against *Cl septique* and *Cl. œdematiens*, however, sulphathiazole is of significantly greater value than the other two

MENINGITIS FOLLOWING SPINAL ANÆSTHESIA

REPORT ON 11 CASES

BY H J BARRIE, B M Oxfd
PATHOLOGIST TO THE ROYAL HOSPITAL, SHEFFIELD

IN July, August and September, 1940, 11 cases of meningitis occurred among the 96 patients who were operated on under spinal anæsthesia in one theatre of the Royal Hospital, Sheffield, during that period The clinical signs and pathological findings resembled each other One case was fatal and an autopsy was obtained

No particular age-group was affected The operations were with three exceptions clean ones, such as repairs of herniæ and fractures The fatal case was a colostomy for inoperable carcinoma of the colon The spinal anæsthetics used were from different batches of light Percaine

Clinical course —In 9 of the patients there was a rise of temperature to 100° F or over within the first three days after operation There were no noticeable symptoms of meningeal irritation at this stage All of them complained of abrupt onset of severe headache between the 7th and 10th days after operation and in most this was associated with drowsiness, irritability, photophobia, neck rigidity and a positive Kernig's sign Blood counts when done showed a polymorphonuclear leucocytosis

All cases, except the fatal one, were free from temperature and symptoms by the 18th day after operation, 9 when examined four weeks after had no residual signs or symptoms apart from slight lateral nystagmus In the fatal case the patient became comatose and died within 7 days of the onset of symptoms

Lumbar puncture was done in 6 cases The fluid wa clear or faintly turbid The protein averaged 100 mg per 100 c cm with the highest reading 160 mg and the lowest 60 mg Chlorides averaged 660 mg per 100 c cm , highest 720 mg , lowest 640 mg Cells averaged 450 per c mm , highest 1100, lowest 9 There wa either slight preponderance of lymphocytes or poly morphs and in the average they equalled each other There was no change in the gold curves except for on mild meningeal reaction No tubercle bacilli or oth organisms seen in films In 2 cases a second lumba puncture within two days showed an increase of prote and fall in the number of cells

AUTOPSY FINDINGS

Female, age 59 Wasted Recent healing left lo paramedian incision Patent left iliac colostomy, and 22 difficulty of joining in small talk, in short, in banalities. He thought that what the deaf person missed should not therefore produce such an intense feeling of isolation and that there must be other reasons for this. He suggested that in the subconscious mind of every human being was the idea that he had a natural right and an inviolable claim to the integrity of his body and its organs. Anyone who lost this integrity experienced a severe psychic shock, increased by the thought of future progress of the defect, and from this shock there developed a traumatic neurosis. Some of the deafened were able to regain their mental and moral equilibrium unaided but for many psychotherapeutic guidance and influence would be necessary.

Dr A. B. STOKES said that his interest in the subject was related to a study of deaf people at the Maudsley Hospital and at the psychiatric department of King's College Hospital. He wished to take a wider viewpoint than that of deafness. The psychological associations of any organic disability considered from the point of view of psychosomatic medicine raised the question whether such associations were specific for the particular disability. But in the clinical field it was found that whatever the organic disability the psychological response considered broadly would take one of few paths, and that these paths remained the same for all organic disabilities and were not specific for any one of them. Thus one might get an anxiety, depressive, hysterical or paranoid response to the onset of blindness, the loss of a leg or to the discovery of a weak heart. Further the pattern of reaction seen could be traced back in time before the disability was established and recognised as a component of the personality, though operating less overtly when there was no hardship. Thus the underlying factor mainly determining the psychological response was the personality make-up. These organic disabilities produced the same results as other forms of stress such as the death of a wife, the crash of a business or the failure to achieve marriage, and each had its root in the personality of the individual concerned. But a particular organic disability, considered as a stress, might pick out a type of person to whom it was a special hardship. Out of the total temperamental responses deafness in such a person evoked the response to which he was temperamentally inclined. A depressive state might arise in a person who in earlier life had shown that type of response to situations involving stress. He might show retardation of thought and action, might have self-depreciatory ideas and be filled with gloom about his present, his past and his future. Similarly according to the individual, hysterical, obsessional or paranoid responses might develop. Yet with all these possible abnormal responses the number of deaf people in a psychiatric clinic was not greater than would be expected from their distribution in the general population. It was people of susceptible personality make-up who broke down under the strain of deafness. When the personality had to adjust to the onset of a stress such as deafness the effect of the speed of onset required consideration. In a general way more acute situations precipitated, in predisposed individuals, an affective response (usually either depression or anxiety) or a hysterical state, whereas a slowly developing deafness enlarged the possiblity of compensation but might bring out, in predisposed people, a paranoid response. Treatment was not approached with pessimism. The lessening of the load by hearing-aids, by lip-reading and by social re-adjustments would allow compensations to develop within the personality. An understanding of the kind of person to be dealt with indicated where the best compensations might be fostered.

Mrs IRENE EWING dealt in a particular rather than a general way with the psychological effects of deafness. They depended on many active and reactive factors in addition to deafness itself—the health and age of a patient, his environment and previous experience, his social attitude and his disposition towards difficulties, his intelligence and physical and mental readiness or unreadiness to acquire new habits; the nature of his work and interests, his resourcefulness and his sense of humour. On the basis of clinical evidence it could be shown that there were special psychological problems arising from deafness which could be simplified or solved by taking into account the information afforded by the otologist's diagnosis together with the results of pure tone tests of hearing by both air- and bone-conduction and tests of hearing for speech with the aided and unaided ear. The results of these tests would yield information on two vital points—the extent to which a deaf patient could be enabled to hear speech in his daily life and the extent to which hearing could be helped by lip-reading, and how far a patient was likely to retain or lose normal speech habits. She emphasised that mental and social life was largely conditioned by one's capacity to communicate freely with others. She analysed the case-histories of patients of all types and ages who had attended the clinic for the deaf at Manchester University under four headings:—

(*a*) Did the kind and degree of the patient's deafness influence or hinder his manner of thinking? How far did it set a limit to the range of his thoughts and interests?

(*b*) Capacity to follow the spoken word.

(*c*) Ability to talk intelligibly and audibly.

(*d*) Capacity to earn one's living—an important factor in mental life.

All the available evidence, including her own personal experience, combined to show that the most serious psychological effect of deafness was the extent to which it restricted speech experience. From this limitation arose all the familiar symptoms of unhappy mental life, uncertainty in action and the distrust of self often seen in deaf patients.

Reviews of Books

The Orientation of Animals

By G. S. FRAENKEL, lecturer in physiology in the department of zoology and applied entomology, Imperial College of Science and Technology, London; and D. L. GUNN, lecturer in zoology, University of Birmingham. London: Humphrey Milford, Oxford University Press. Pp. 352. 21*s*.

THIS is an engaging book which could be described in half a dozen ways, so truly have the authors transcribed their knowledge, their love of law and order, their philosophical beliefs and their enthusiasm. Orientation is not used in the restricted sense which the purely "human physiologist" tends to take for granted; the book is about the reactions of animals, chiefly invertebrates, to influences like light, temperature and humidity. Equilibrium of mammals in relation to gravity gets short shrift, and the reader will gain more information on this subject from other sources.[1] From Fraenkel and Gunn, however, he will learn almost everything else about orientation, and when he is not engrossed in such problems as what guides the bed-bug, or how the ant finds his way home, he will find himself wanting to argue with the authors about free will or about the degree of probability that a certain type of flatworm would migrate from light to darkness if it had ideal properties. Terminology is their first preoccupation, and in classifying the types of reaction whereby animals become oriented (or orientated, as they inexplicably prefer to say) with reference to a stimulus they adhere to terms which have the maximum of objectivity and imply the minimum of anthropomorphism; indeed, they are, if anything, at too great pains not to be misunderstood. The second part of the book is more detailed and deals with the conditioning stimulus—its type, its possible modes of action, and its manipulation so as to yield the information required. All kinds of experiments are discussed, with a wealth of example and illustration, and a bibliography, which make the book valuable for reference.

The World and the Atom

By C. MOLLER and EBBE RASMUSSEN. London: George Allen and Unwin. Pp. 199. 10*s*. 6*d*.

THE world of Moller and Rasmussen is not the world about us but the world of the atom itself. They have succeeded, not so much in giving us a picture of atoms as they exist, as in gradually unfolding the discoveries that have led to the prevalent ideas of the sort of processes going on inside atoms. The discovery of the electron opened the epoch of research into the way of an atom, and it is common knowledge that this discovery alone and with starch and diastase or benzpyrene, on the semi-solid medium alone or with diastase or *B prodigiosus*, or both

---

[1] See Ellis, M. *Lancet*, 1940, 2, 371.

On Barret and Yarbrough's medium (1921) there was survival for 2 days, but no multiplication was observed On Boeck and Drbohlav's medium with the addition of rice-starch, cultures were obtained but were irregular and subculture was not always successful The balantidium grew at the bottom of the medium and up to 10 protozoa were found on coverslip preparations Cultures lived up to 11 days, the average life being 7 days The addition of a trace of benzpyrene improved the culture, up to 50 protozoa per coverslip preparation were found

We found the semi-solid medium plus Taka-diastase (1 5000 medium) much more satisfactory than Boeck and Drbohlav's medium for the culture of *Balantidium coli* Coverslip preparations from the bottom of the medium showed up to 250 protozoa per preparation, cultures lived up to 28 days, the average life of a culture being 10 days The addition of diastase is a great advantage, for it both enriches and prolongs the life of the culture Without diastase preparations showed only 5 or 6 protozoa per coverslip preparation and the average life of a culture was only 5 days

By far the best results were obtained with the semi-solid, serum-starch medium inoculated a day or two previously with *B prodigiosus* The balantidium grew throughout the whole column of the medium and showed up to 450 protozoa per coverslip preparation Cultures lived up to 28 days and the average life of a culture was 12 days The addition of diastase appreciably improves the culture and lengthens its life Encystment occurs in cultures but conjugation was not found Maximum multiplication takes place at a pH of 6 7–7 0 and the cultures die out when the pH approaches 5 0 Our strain of *Balantidium coli* was not very sensitive to temperature and grew both at 30° C and at 37° C, the best cultures being obtained at 30° C

With all these three protozoa a very small inoculum suffices for producing cultures on the semi-solid medium plus *B prodigiosus*

SUMMARY

A simple medium is described suitable for the cultivation of *Entamœba histolytica*, *Trichomonas intestinalis* and *Balantidium coli*

This work was carried out with a grant from the Dazian Foundation, New York

DYSENTERY DUE TO *B DYSENTERIÆ* NEWCASTLE

PREVALENCE IN EDINBURGH

BY A J RHODES, M B Edin, M R C P E
LECTURER IN BACTERIOLOGY, UNIVERSITY OF EDINBURGH

THE organism now known as the Newcastle dysentery bacillus was first recognised by Clayton and Warren (1929a, b) in an outbreak of dysentery in Newcastle-on-Tyne A number of strains of this bacillus have since been extensively studied by Boyd (1936, 1938, 1940), and following his work on antigenic structure it is now generally held to belong to the Flexner group, although admittedly differing in biochemical properties from typical *Bacillus dysenteriæ* Flexner

Of recent years the Newcastle bacillus has been isolated on various occasions from cases of dysentery in Great Britain—e g, Scott 1938—and it is the object of this note now to record its present prevalence in Edinburgh Thus, in 1940, of 187 cases of bacillary dysentery proved in this laboratory by isolation of the causal agent from the fæces, 113 were found to be due to *B dysenteriæ* Flexner, 47 to *B dysenteriæ* Newcastle, and only 27 to *B dysenteriæ* Sonne It can be seen, therefore, that at the moment the Newcastle bacillus is a common cause of dysenteric infection in this city

The strains of *B dysenteriæ* Newcastle isolated in this laboratory have the following characteristic properties After 24 hours' growth at 37° C in the usual range of peptone water "sugar" media the only change noted is fermentation of glucose with formation of acid and usually a small bubble of gas at the top of the Durham tube On further incubation for 3 to 4 days weak acid-production may occur with dulcite, again with a bubble of gas Certain strains may ferment maltose, with weak acid-production, a bubble of gas is only produced by a few strains, the time taken for this reaction varies from 24 hours to 5 days All strains are non-motile and do not form indole or ferment lactose, saccharose, or mannite Final identification of strains having these characters is now rendered straightforward by the use of a specific antiserum prepared by the Oxford Standards Laboratory An agglutination test is set up with a saline suspension of the organism and varying dilutions of the Newcastle antiserum, incubation being carried out at 55° C for 4–6 hours The tests are read after standing at room temperature overnight, well marked agglutination of the granular type usually taking place to the titre of the serum

I am informed that, clinically, these cases of infection with *B dysenteriæ* Newcastle are of the prevalent mild type, and cannot be distinguished from those due to Flexner's or Sonne's bacillus

I am indebted to Dr Alexander Joe, medical superintendent of Edinburgh City Fever Hospital, for the clinical information contained in this note

Medical Societies

ROYAL SOCIETY OF MEDICINE

AT a meeting of the Section of Otology held on Feb 7 with Mr LIONEL COLLEDGE, the president, in the chair, a discussion on the

Psychological Aspects of Deafness

was opened by Prof HUGO FREY He said that since a great part of all our sense impressions passed through one hearing organ a study of the psychology of deaf people must be worth while from a theoretical and practical point of view There was nothing in the literature dealing exclusively with the subject though there were references to aspects of it in the writings of Nager, Eichholz and the Ewings, and of special interest were the confessions of the deaf themselves particularly those of Beethoven and Margaret T Monro In dealing with the subject he thought it essential to avoid sentimentality The deaf were not a uniform group On the one hand deaf mutes form a separate community among the hearing people, they were almost a separate variety of the species He asked "What is their conception of the outer world, of an unacoustic, mute world?" Deaf mutes did not usually suffer from mental depression because of their deafness Psychic abnormalities found in some of them were probably more an outcome of a general degenerative constitution Therefore even the highest degree of deafness did not in itself necessarily lead to a depressive state of mind Further, many of those who became deaf in later life—the deafened—still enjoyed life and all it had to offer them But in this group there were many who suffered from mental depression This, he thought, was due partly to their difficulties, partly to their exaggerated estimate of the extent of their defect and of its personal and social consequences Their main complaint was their isolation, the difficulty or impossibility of enjoying company and social life But it seemed to him that their loss was not really so great Intellectual life in our time depended much more on the optic sense than on the acoustic Science, politics, news and even amusement all could be conveyed to us by the written and not the spoken word The higher the standard of culture the more important because the optic and the less important the acoustic sense Often their intensively deplored isolation concerned the more trivial affairs of daily existence, the

GENTIAN VIOLET JELLY

with

TRADE MARK **'MERTHIOLATE'** BRAND

SODIUM ETHYL MERCURITHIOSALICYLATE

FOR THE TREATMENT OF BURNS

This Jelly, containing one per cent Gentian Violet, provides a convenient method of applying the dye to burned areas Particularly adapted for use in burns about the face and hands, areas where the skin is thin, and in body flexures The addition of 'Merthiolate,' which is an excellent general germicide with a low toxicity for tissues, enhances the value of the product and further lessens the possibility of infection

Supplied in one-ounce and five-ounce collapsible tubes

SCHERING LIMITED, 185-192 High Holborn, London, W.C.1

was made by the late Sir Joseph Thomson There is a bad blemish in the book where we read, on p 36, " By means of such experiments, which we owe especially to J J Thomson of England, the velocity of the (cathode) rays was now successfully calculated " This is followed on p 37 by " we may indeed assume that electricity consists of infinitesimal particles For this assumption proof was adduced by means of a great experiment in which Millikan of America succeeded in directly measuring the quantity of electricity pertaining to an individual electron " This is a complete travesty of the real position The foreword is by Prof Niels Bohr The book is almost devoid of mathematics and is written in conversational style, the authors remind us that spectroscopists, in the not very distant past, were regarded as " not far removed from cranks," but nowadays they are allowed into the society of the elect, in fact, whenever a new particle is discovered, the first question is " What *will* the spectroscopist say about it ? " The new physical discoveries about the atom have given the spectroscopist something to bite on, something much more tractable—or malleable—than the old, hard, elastic spheres of Kelvin-side In the last chapter a reasoned answer is given to the popular inquiry about releasing appreciable energy from excited, radioactive or bombarded atoms—apparently there is no hope

Fractures

By GEORGE PERKINS, Ch M Oxfd, F R C S, assistant orthopædic surgeon to St Thomas's Hospital London Humphrey Milford, Oxford University Press Pp 381 20*s*

THE author has compressed much into this small volume He writes clearly and concisely, but the short abrupt sentences may sometimes read more dogmatically than he intended His advice, allowing for the personal bias —which is as much a quality as a defect in surgeons—is sound and conservative, he always advocates the little less rather than the little more in treatment Several points about the book invite criticism, however One is the odd arrangement by which—to bring the diagrams opposite the relevant text—whole pages are left blank except for a line or two More serious objection can be taken to the section on skull fractures which is so sketchy as to be in places misleading, and the section on jaw fractures will seem altogether too lighthearted in tone to those who have treated such cases, the diagram of the four-tailed bandage contains its own condemnation The long bones are dealt with well, and the diagrams, though sometimes rough, generally make their point in a telling manner

Textbook of Medicine

(5th ed) Edited by J J CONYBEARE, M C, D M Oxfd, F R C P, physician to Guy's Hospital, London Edinburgh E and S Livingstone Pp 1131 24*s*

THERE are few changes in this edition Dr Maurice Campbell has succeeded Dr W H Craib as part author of the cardiovascular section, which has been worked over afresh The sulphonamide drugs have, naturally, introduced themselves at many points Blood-transfusion, as a topical subject, has been presented anew, concisely and effectively, by Dr F A Knott The sections on hæmatemesis, diverticulitis, and anorexia nervosa are rewritten, in the first of these Dr Conybeare makes due mention of Meulengracht but still prefers, himself, to give his morphinised patients nothing but sips of water and scraps of ice for 48 hours after they have vomited blood

The book remains one of the best medium-sized textbooks for the junior student

Principles of Hematology

(2nd ed) By RUSSELL L HADEN, M D London Henry Kimpton Pp 362 21*s*

THIS American textbook presents the old facts in a new guise and the new facts simply and with understanding It caters for students rather than for the specialist, but the novel and effective diagrams, charts and microphotographs compel attention and make important points arresting Like many good teachers, Dr Haden invites the charge of over-simplification of his subject but he disarms the omission-hunter by admitting that difficult technical methods are not included It is probably wise to limit the number of leukæmias the student should try to remember, but is there anything to be gained by keeping him in the dark about the value of sternal puncture in diagnosis ? We remember facts better than theories, but until it has been conclusively shown that vitamin K is converted in the liver into prothrombin it is best to keep it among the theories and risk forgetting what may have to be forgotten in any case Throughout emphasis is placed on the technique of examination, and the reader is constantly reminded that clinical interpretation requires accurate laboratory data and that both must be carefully weighed before diagnosis is made Case-records of more than 100 patients suffering from the various blood dyscrasias are divided into groups so that the differential diagnosis of splenomegaly, for example, may be readily made The repetition necessary to this method detracts a little from its decisiveness but it will teach the student what to expect and to look for in the wards The sections which deal with treatment are among the best

Hæmorrhoids and their Treatment

The Varicose Syndrome of the Rectum By KASPER BLOND, M D Vienna, formerly first assistant, Rothschild Hospital, Vienna, hon consulting surgeon, Municipal Hospital, Vienna Bristol John Wright and Sons Pp 140 15*s*

THIS book deals with the injection treatment of hæmorrhoids, fissure and fistula It advocates ambulatory treatment for these conditions and states that the operation for hæmorrhoids, for example, is not only non radical but is often followed by complications The author's complete disregard for modern advances in our knowledge of the surgical anatomy and surgical operations for hæmorrhoids, fissure and fistula is owing to his conception of a varicose syndrome of the rectum, upon which he bases the ætiology of all these conditions The translator, Mr E Stanley Lee, F R C S, in his preface, hopes that the theory put forward will arouse controversy, and well it may, since it cuts across all the established principles of proctology

Rectal Surgery

By W E MILES, F R C S, F R C S I, F A C S, senior surgeon to the Gordon Hospital for Cancer, and consulting surgeon to the Royal Cancer Hospital London Cassell and Co Pp 359 17*s* 6*d*

THIS book is an interesting and clear record of the life experience of an eminent specialist in rectal surgery Naturally on many points he expresses personal opinions, and some of these may not be acceptable to all The matter is well presented, and the illustrations and diagrams are particularly good

Cushny's Pharmacology and Therapeutics

(12th ed) Revised by G W EDMUNDS, M D, and J A GUNN, M D, D Sc, F R C P London J and A Churchill Pp 852 30*s*

THE decision in many medical schools to dissociate the teaching of pure pharmacology from therapeutics is important, and its repercussions are apparent in the type of textbook now appearing " Cushny " represents the old school Although an experimental pharmacologist, the author was fully alive to the importance of correlating his subject with its therapeutic application, and a substantial proportion of his book deals with medical treatment In the new edition—longer by some 40 pages, and containing a new section on sulphanilamide, and amplified chapters on the vitamins and internal secretions—the editors have worthily upheld the traditions of the work It remains one of the best accounts of the subject in the English language Against this type of book it is often said that the arrangement of the material is dull and out of touch with the realities of clinical experience No doubt there is some truth in this, but the drawback is inherent in the subject itself—the discovery of a simple and rational classification of the materia medica has defeated some of our ablest intellects Nevertheless, where angels fear to tread there has been not a little coming and going, the student is overwhelmed with the choice of textbooks, and many of the authors purport to have found a royal road to success in this line of study It is natural that the deficiencies of these manuals should only become apparent when the student is able to look back

THE LANCET

LONDON SATURDAY, FEBRUARY 22, 1941

THE HERITABLE FACTOR IN EPILEPSY

THE last 25 years have seen the steady growth of "symptomatic" epilepsy at the expense of the "idiopathic" group, until in certain circles, especially in France, the existence of the latter has been denied altogether Most clinicians would, however, recognise that in the majority of cases there is an interplay of an inherited factor with some local want of development, trauma or disease in the brain The assessment of the heritable factor has long been the subject of controversy, but startling light has been thrown on it by LENNOX, GIBBS AND GIBBS[1] They find that the incidence of epilepsy among the near relatives (parents, siblings and children) of 2130 epileptics is 2 4%, or about five times that in the general population Clinical evidence of this sort is likely to be incomplete and some of the findings are open to question Are fainting fits or an occasional convulsion in infancy, for instance, to be called epilepsy? More valuable as evidence in the clinical field of the heritable factor is the observation that if one of identical twins has epilepsy, in 70% of cases the other twin will be similarly affected

he establishment of objective laboratory evidence pilepsy, or of a predisposition to epilepsy, in the r relatives of epileptics would obviously be of -class importance Such objective laboratory lence is, according to LENNOX and his colleagues, vided by the electroencephalograph Electroephalograms vary, they admit, with the age of the ent, with attention, wakefulness and cerebral ivity generally, and with pulmonary ventilation, taken under standard conditions in the same ent they are constant and show individuality, ugh not indeed of the fingerprint standard Elecencephalograms of identical twins, they note, are ays similar whether the tracings are normal or ormal, and if they are abnormal, the same type dysrhythmia is always present, even when trauma other factor has induced what is on the face of it ymptomatic epilepsy in one of the twins They ve investigated by electroencephalography 183 r relatives of 94 epileptics, in most of whom the ease started in early life and—rather surprisly—only 2 of whom showed normal encephalos themselves The relatives included 143 parents, siblings and 4 children, and their ages ranged from o 78 years As a control group, 100 people were ilarly investigated whose families were believed be free from epilepsy In every case records were de from six areas of the cortex for at least twenty nutes, and the dominant frequency, constancy and ltage of the waves were the factors considered in ciding whether the tracings should be classed as rmal or abnormal Towards the end of each cord there was a short period of voluntary pulonary overventilation, but records made during s period were not classified as abnormal unless they showed the typical "wave and spike" formation of petit mal To obtain reliable records, free from artefacts, involves a high degree of laboratory technique, and their classification needs considerable experience Skilled as they are, the authors had to relegate about 7% of their records to a "doubtful" class

The results of the investigation are remarkable—60% of the relatives show abnormal tracings (2 2% of them had clinical epilepsy) as against only 10% of the control group The age of the relatives appears to have little influence on the incidence of dysrhythmia, nor does the age of onset of the disease in the epileptics themselves Dysrhythmia is as frequent among the relatives of those suffering from symptomatic epilepsy as of those classified as idiopathic The authors believe that symptomatic cases whose epilepsy begins in early life have, clinically, three times as many epileptic relatives as people in the general population, and idiopathic cases five times as many Sufferers from symptomatic epilepsy starting in later life, however, have not an unusual number of epileptic relatives Dysrhythmia is rather more frequent among the relatives of female than of male patients, and among the female relatives than the male The heritable factor, therefore, is rather stronger in the female But it does not seem to preponderate among relatives of the same sex as the patient, in other words, there is no sex-linkage In 55 out of the 94 cases both parents were tested In only 5% of these were the tracings from both parents normal and in no less than 35% both were abnormal The experience with identical twins suggested that there might be familial types of dysrhythmia, but the evidence of this is inconclusive, complicated as it must be by mixed inheritance and by the tendency of petit mal to disappear in adult life Nor is it possible to say whether inheritance varies with the degree of abnormality

What does dysrhythmia mean for the individual who is unfortunate enough to possess it? Undoubtedly it may mean potential epilepsy, and possibly behaviour disorders, migraine or even psychosis, and in younger patients these possibilities are much nearer probabilities and may even call for prophylactic medication In older patients who show no other sign of abnormality, fits are unlikely to develop unless they get an added cerebral lesion These findings, if they are confirmed and accepted, open up far-reaching implications 2 4% of the near relatives of epileptics have epilepsy, 60% (or twenty-five times as many) have dysrhythmia, therefore, if 0 5% of the population has epilepsy about 12 5% have dysrhythmia—a figure which corresponds fairly to the 10% found in the control group This gives about a 1 in 100 chance of two dysrhythmics mating, yet no less than 35% of the epileptics in the present series had two dysrhythmic parents—a fact suggesting, perhaps, mutual attraction of similar types of personality It looks as if a dysrhythmic (a potential epileptic or carrier of epilepsy) should ask for electroencephalographic tracings of his betrothed when contemplating marriage Here is a new and not altogether agreeable field for the family medical adviser, who would also have the uncongenial task of telling the parents of an epileptic child which of them was responsible for his disease, and which of his brothers and sisters were potential epileptics or

been overcome—although some British and American textbooks still retain quite out-of-date descriptions of the development of the red blood-cells. The material on which GILMOUR's ideas are based is essentially similar to that studied by his predecessors, so that it is unlikely that hæmatologists, particularly those interested in pathology, will, without stronger evidence, be induced to abandon the simpler schemes of erythrocyte development now current; they will no doubt prefer to wait for further elucidation of the definitive megaloblast.

A LIPOID DISORDER

IN England the name gargoylism has been associated for some years with a polydystrophy first described in 1919 by GERTRUD HURLER, and known on the continent as Hurler's syndrome. Children affected are usually mentally defective and have congenital bony deformities, large livers and spleens, strangely ugly faces and clouding of the cornea. There is, however, as we have previously noted,[1] *a forme fruste* in which mental defect may be slight or absent and the cornea may be unaffected. Few of the typical cases survive into adult life; their mental powers develop slowly for a few years, then gradually deteriorate, and death before the age of ten years is common, usually from intercurrent infection. Growth is normal for the first year and then slows up, so that all who survive infancy are dwarfed. The head of an affected child is large and his face flat; the bridge of his nose is depressed, profuse nasal discharge usually accompanying the deformity, and the front of the jaw is straight instead of curved, with the teeth set along it at intervals like palings in a fence. Commonly he cannot open his mouth more than a degree or two owing to partial fixation of the maxillary joint. His lips are thick and his full cheeks sag a little, producing a deep nasolabial fold. His eyes, usually large, have a steamy or ground-glass appearance of the cornea, and his broad eyebrows of coarse sparse hairs give his face an odd look of character. His ears are big and set low. His abdomen is large and umbilical hernia is common. He has rather short arms with the elbow-joints fixed in semiflexion; the mobility of his leg joints is also impaired so that his gait is crouching, clumsy and ungainly. Owing to dysplasia of the upper lumbar vertebræ there is usually dorsolumbar kyphosis; the rib margins are flared and the child may be pigeon-chested. The liver and spleen are usually easily palpable. Radiography often shows a long shallow sella turcica, broadening of the ribs and wedge-shaped flattening of the upper lumbar vertebræ, some of which bear an anterior hook-like process. The limb bones are also thickened and bossed, especially near the joints, owing to irregular epiphyseal ossification. So-called stigmata of degeneration, such as hypertrichosis and congenital heart defects, may be present; club foot and cervical rib have each been recorded once. Sexual development is likely to be delayed in those who survive puberty. In disposition these children are grave and gentle, lacking the gaiety often seen in the mongol and the microcephalic. Those showing the complete syndrome seldom learn to speak more than a few words, but they may acquire sphincter control for a time.

The condition is rare, although 6 new cases have lately been reported, 5 by HENDERSON[2] and 1 by ELLIS.[3] HENDERSON has found 48 authentic cases reported besides his own; 9 others were inadequately authenticated. Two or three children showing the syndrome may be born in one family, often interspersed between normal brothers and sisters. Twins have twice been affected, in one instance both children and in the other one of the pair showing the syndrome. Boys are slightly, but not significantly, more often affected than girls. In 5 cases the parents have been consanguineous, and the available evidence suggests that the condition is recessively inherited.

Only a few cases have been investigated fully post mortem, but the striking pathological finding is a deposition of lipoid, variably distributed. The lipoid is both intracellular and extracellular, and the intracellular deposits resemble the lipoid found in the juvenile form of amaurotic family idiocy. In the brains of 4 of his cases HENDERSON found the deposits *to be extracellular and chiefly perivascular.* Lipoid deposits have also been found in the anterior lobe of the pituitary, the liver, spleen, myocardium, lungs, thymus, testis and cornea, though these sites are not constant. The central nervous system shows degenerative changes in nerve-cells, particularly those of the basal ganglia and brain stem and the deeper layers of the cortex; the optic thalamus and hypothalamus may show gliosis. HENDERSON considers that the condition, like amaurotic family idiocy, is likely to prove to be a disorder of lipoid metabolism. He favours the name gargoylism, which was first used by ELLIS, SHELDON and CAPON in 1936,[4] but there are substantial objections to it. A minor one is its inaccuracy, a gargoyle, of course, being a spout which may or may not be decorated with a face, but which is in any case prominent and projecting. These children are exceptionally flat in the face; if we must be architectural they resemble some of the heads used to decorate corbels rather than gargoyles. A more serious objection is the offence which the name gives to the parents of these children, and, where intelligence is normal, to the children themselves. Rightly or wrongly we associate the word gargoyle with gross and grotesque ugliness. Those who have interviewed parents of such children know how wounding the name has proved. It should be replaced by some neutral and scientific designation. Hurler's lipoidosis might be appropriate. This would make a second disease named after a woman discoverer, the other being Klumpke's paralysis.

IN a short review of war psychiatry, reprinted from the *Surgeons' Hall Journal* (Oct.-Dec. Term 1940), Dr. H. Stalker aims at giving the physician without expert knowledge an idea of the special problems of war-time. Using psychiatric literature of the last war and other more recent publications, and illustrating some points with a few observations of his own, he gives the main facts and touches all important questions. His views are sound and well founded. It would, however, be regrettable if the responsible authorities concluded from the smooth and pleasant reading this paper makes that everything practicable is being done, and that psychiatry is being used to the best advantage in the disposal of man power.

carriers of epilepsy on to the next generation Perhaps it is just as well that electroencephalographic investigations are not as simple as Wassermann tests, but require an expensive apparatus, highly perfected laboratory technique and long experience For the eugenist a fascinating field opens up Epilepsy is usually regarded as a Mendelian recessive trait, but this widespread dysrhythmia looks more like a dominant To breed epilepsy out by sterilisation or segregation of its victims has long been a eugenic day-dream, but if all dysrhythmics are potential carriers we should need a whole battery of machines to sort out the four million miscreants in our own country We must await confirmation by independent observers of the findings in this paper, and the criticism of other workers in the same field For the clinician, meanwhile, the heritable factor in epilepsy has achieved a new importance, and those who spoke slightingly of the idiopathic disease have been confounded

INFANCY OF THE BLOOD-CELL

Few subjects have been more debated among anatomists than the development of the blood-cells, and since many diseases of the blood are disturbances of maturation of the blood-cells pathologists are also immediately concerned Much of the controversy has undoubtedly been due to the fact that the results obtained from the study of birds and small mammals are not applicable in detail to man Gilmour[1] has now been able to examine a group of human embryos from early presomite stages (from Professor Frazer's collection) up to full maturity He finds that in the very early embryos blood islands form in the yolk sac, and from their walls the first hæmocytoblasts (primitive blood-cells capable of differentiating into any of the recognised types) arise , at first they develop into erythroblasts—called " primitive megaloblasts "—and some histiocytes , some of these primitive megaloblasts escape into the connective tissue and there proliferate, such foci of erythropoiesis remaining present until quite late stages In the 3–9 mm embryos, after the circulation is established, the cells in the blood-vessels are mostly primitive megaloblasts that appear to be hæmoglobinated After the 10 mm (six week) stage hæmocytoblasts appear in the liver and from them cells are developed that differ from the primitive megaloblasts in size and structural details and are called " definitive " The earlier basophilic cells of this definitive group are called " primary erythroblasts " and they ripen into " normoblasts " whose nucleus is pyknotic and whose cytoplasm contains eosinophilic hæmoglobin , sometimes, however, these primary erythroblasts develop eosinophilic cytoplasm before the nucleus becomes pyknotic, and then the resulting cells are again called megaloblasts, but " definitive megaloblasts " this time At this stage also, megakaryocytes appear in the liver Between the 10 and 26 mm (eight week) stages the formation of granular leucocytes begins in the liver and in various connective tissues, lymphocytes appear in the blood, and nucleated red cells in the blood fall to about 25%, some primitive megaloblasts being still present In the next four weeks considerable changes occur , hæmopoiesis begins in the bone-marrow—first in the clavicle—and all types of blood-cells, including megakaryocytes are found there, granular leucocytes appear in the blood and the nucleated red cells fall still further to 5% (all definitive megaloblasts and primary erythroblasts), lymphocytes are forming in the lymph-glands No very active hæmopoiesis was, however, found in the spleen or kidney at this period At the 200 mm (twenty three week) stage hæmopoiesis in the liver reaches its peak and thereafter decreases From this stage hæmopoiesis becomes steadily more adult, erythroblast formation in the general connective tissue has ceased, active marrow is present in long and flat bones, the malpighian bodies in the spleen are forming lymphocytes, and nucleated red cells in the blood are less than 1% Sometimes slight hæmopoiesis is still present in the liver at birth

In general outline this detailed account agrees with most previous accounts based on the view that the blood-cells are derived from a hæmocytoblast that is not identical with the lymphocyte Gilmour finds that, after the 48 mm stage, erythropoiesis and leucopoiesis are exclusively extravascular, thus differing from Doan and co-workers[2] who thought the former was intravascular The part of Gilmour's scheme that is likely to meet most criticism is his conception of erythropoiesis Naegeli, Ferrata, and Downey have been the main supporters of the view that the megaloblast is the erythroblast of the early human embryo, up to the 10 mm stage, and that the normoblasts are the definitive series which replaces them after this stage These megaloblasts are similar to the cells which appear in the bone marrow in untreated pernicious anæmia , they are derived from the same basophilic precursor that gives rise to the normoblasts (or primary erythroblasts) Both normoblasts and megaloblasts mature by becoming hæmoglobinated, and eventually losing their nuclei Normoblasts do not change into megaloblasts, or vice versa This type of scheme has received considerable support from pathological workers since it has enabled them to construct a workable theory of the ætiology of the anæmias Gilmour's " primitive megaloblasts " seem to correspond to the megaloblasts as understood by most hæmatologists , in addition there is his " definitive " group of megaloblasts that are developed from primary erythroblasts and represented as being capable of maturing into megalocytes or—via a pyknotic normoblast stage—into normocytes Between the 48 and 180 mm stages this process of development of normoblasts by shrinkage of definitive megaloblasts is important, he terms it " megalo-normoblastic erythropoiesis "

Superficially then it looks as if Gilmour differs from all present-day workers, with the exception of Lambin and de Weerdt,[3] in not regarding the megaloblast and normoblast series of cells as distinct, but in reality the only difference is that his definitive megaloblasts do not appear in previous schemes Since these cells are only indirectly related to the primitive megaloblasts it is a pity that some other name was not given to them For this conception of megalo-normoblastic erythropoiesis is likely to cause unnecessary confusion at a time when the confusion in nomenclature caused by the use of the name megaloblast for the basophilic early erythroblasts has at last whether there is a panacea for dental ills. The vagaries of the single case must be assessed by the dental surgeon o the best of his ability, and the treatment varied ccordingly.

CHLOROFORM IN OBSTETRICS

NO-ONE would willingly reopen the old controversy about whether to use or not to use chloroform in labour, but Sheehan's[1] paper on acute yellow atrophy and delayed chloroform poisoning should not be overlooked either by habitual devotees of chloroform or by those who use it but rarely and then with misgivings. Both true acute yellow atrophy and obstetric yellow atrophy, which is a definite and separate entity, can be associated with labour without chloroform anæsthesia; they are similar clinically but the former arises from a gross liver necrosis and is very rare in pregnancy, the latter from a gross fatty change in the liver with an entire absence of necrosis. Sheehan describes delayed chloroform poisoning as being far commoner in obstetric than other types of patients, and maintains that this is not generally realised because the liver lesion is not always recognised as due to chloroform and is ascribed to the obstetric complications. Three types of lesion are associated with three types of patient. In the first there is an isolated cell lesion with a distinctive necrosis of scattered individual liver cells. This is the rarest form of delayed chloroform poisoning and occurs as the result of overdose in a healthy subject. Sheehan describes two cases, one dying 18 hours and the other 2 days after chloroform anæsthesia for delivery. The commonest type is the second, a mid-zonal necrosis. Of the nine cases cited by Sheehan all had a long labour before the administration of chloroform began (a mean of 3¾ days). Two of the patients died within a day of having chloroform; the others developed typical delayed chloroform poisoning and died 3–5 days after the administration. Some of these patients had relatively short anæsthesia, the longest being 45 min., and there was no clear relation between the amount of chloroform used and the severity of the illness. All of them had been almost starved for a few days before the chloroform was given and were probably in a condition of starvation acidosis, in which there is a nitrogen retention apparently due to oliguria from pressure on the trigone and ureteric orifices.[2] The third type, with a central necrosis, was found in two patients, each of whom had hyperemesis; they aborted with chloroform without preliminary intravenous glucose and died 3–4 days later with the clinical picture of delayed chloroform poisoning. These patients have a metabolic disturbance which includes both an acidosis and a gross uræmia, apparently related to the anhydræmia. The gross fatty infiltration of the liver seen in delayed chloroform poisoning in children apparently does not arise in obstetrics. Sheehan concludes that a healthy pregnant woman is normally resistant to chloroform, and the risk of liver damage from chloroform anæsthesia in such a patient is therefore remote, but that this risk is very real in patients who have a gross metabolic disturbance before their anæsthetic begins. The common factor in all cases, and one which is easily obviated and treated, is a starvation acidosis. He urges that as much attention should be given to the anæsthetic as to the obstetric problems. The history of the few days prior to anæsthesia is all-important, for, as Sheehan says, "the patient who has been left in labour for a few days without adequate treatment is extremely susceptible to what may be regarded rather as a poisoning by delayed chloroform than as a delayed poisoning by chloroform." He accounts for the greater frequency of delayed chloroform poisoning in obstetric hospitals than in domiciliary midwifery on the ground that it is to the hospitals that patients are brought for delivery when there has been long delay in labour and when starvation acidosis has therefore developed. If the history of the previous two or three days is studied he maintains that almost every case can be foreseen before the anæsthetic is begun, and that the general prohibition of the use of chloroform for fear of delayed poisoning is wholly unnecessary. Those who advocate chloroform in obstetrics can therefore point triumphantly to this article as vindicating their opinion, provided adequate precautions are taken. Sheehan does not touch on the incidence of immediate fatalities under chloroform anæsthesia and these are responsible for the opinion of many that the use of chloroform is unjustified because they cannot be foreseen, and because experience on the part of the anæsthetist cannot prevent them. Nevertheless, sudden death under chloroform in the labouring woman is extremely rare. These patients and these alone look forward eagerly to the arrival of the anæsthetist, and hence in them there is no fear of the anæsthetic itself, and therefore no outpouring of adrenaline into the bloodstream during induction. And it is the simultaneous action of adrenaline and chloroform on the heart which seems most likely to lead to fatal ventricular fibrillation.[3]

SEROUS FLUID

TEXTBOOK accounts of the different pathological fluids found in serous cavities tend to be clear-cut because most of them are a legacy accepted without criticism from older authors, but the clinician has good reasons for disillusion. When a pathogenic organism is isolated, or, more rarely, when a diagnostic group of tissue cells is seen, diagnosis is simple, but commonly the evidence is only circumstantial and not too trustworthy. Paddock's[4] review of more than 1500 fluids collected over 25 years is one of the few critical analyses of the accepted data. Apart from looking at a fluid the usual starting-point is the specific gravity and it is often held that 1016 is the dividing line between dropsical (transudative) and infected (exudative) fluids. Paddock found that 313 cardiac fluids from the pleural cavity had an average specific gravity of 1010 but 10% were 1016 or more, while tuberculous fluids averaged 1020, with 10% 1016 or less. In ascites 95% of cirrhotic fluids were in the transudative range while neoplastic fluids both from the pleura and peritoneum were evenly divided between the exudative and transudative specific gravities. A curious discrepancy exists between cardiac fluids from the chest and those from the abdomen, a third of the latter having a specific gravity of 1016 or more, with a correspondingly high protein content. It seems then that the boundary between the specific gravities of transudates and exudates is a broad elastic band rather than a sharp line. The cytological and biochemical findings in aspirated fluids are also variable though there are a few general indications to help in the individual case. Erythrocyte counts of over 10,000 per c.mm. were found by Paddock in two-thirds of neoplastic fluids and in a third of cirrhotic and pulmonary-infection fluids, but the possibility of damage by the puncturing needle may lead to doubt of the accuracy of all such figures. White cell counts are more useful, but in 85% of fluids associated with acute pulmonary infection, in 73% with tuberculosis and in 42% of neoplastic fluids there was a total count of more than 1000 per c.mm. The high polymorphonuclear leucocytosis in pyogenic infections is a great aid but there may be such a neutrophilia in non-infected cirrhotic fluids and in early tuberculous effusions, and Paddock records 9 proved cases of tuberculosis with more than half the cells polymorphonuclear. It follows that even with the most familiar pictures one has to be on guard in interpreting cellular findings. The same can be said of the protein content of the various types of effusions

COW'S MILK FOR NEONATAL HÆMORRHAGE

WORK on vitamin K in relation to the hæmorrhagic disease of the newborn has not yet cleared up the whole story of the pathogenesis of this condition Salomonsen of Oslo, who has already shown that the administration of small quantities of cow's milk to newborn infants during the first four days of life can almost completely prevent the hypoprothrombinæmia and prolonged coagulation-time of that period, now reports[1] that this prophylactic method is more effective in summer than in winter, when, in fact, the physiological prolongation of coagulation-time is greater than in the warmer months It is suggested that cow's milk produces its effect by inducing the growth of bacterial flora in the intestinal tract, thus stimulating the endogenous production of vitamin K, but Salomonsen does not explain how this is achieved, and indeed the details given in his latest paper make the whole subject more baffling than before He found that when cow's milk additions were made to the diet for the first four days of life there were certain practical difficulties when breast-feeding was successfully instituted In his most recent investigations, therefore, he has limited the administration of cow's milk to the first two days On the first day he gave 20 grammes of equal parts of milk and water on three occasions and on the second day 40 g of the same milk mixture three times He added 5% of sugar to the diluted milk, and—most important—the milk was raised to boiling point for two minutes in a water bath Investigations of the coagulation-time in a group of babies receiving cow's milk in this way shows an almost immediate effect compared with a control group fed exclusively on mother's milk The sharp rise in coagulation-time on the third and fourth days of life found in the control group did not occur in the group receiving cow's milk, and not until the eighth day did the values for the coagulation-time in the two groups coincide Spontaneous hæmorrhage occurred in 2 out of 10 infants of the control group—surely a surprisingly high proportion—and in none of the babies receiving cow's milk These results were obtained in the winter and were not so spectacular as in the previous summer investigations since normal levels for coagulation-time were not obtained Nevertheless it was sufficiently reduced to prevent the occurrence of spontaneous hæmorrhages and the method was therefore adopted as a routine in the obstetrical department of Rikshospitalet in Oslo Over a period of six months, beginning in November, there was no case of hæmorrhagic disease in the newborn among 1005 live births, while in the same six months in the previous five years there had been 40 cases in a total of 4783 live births The results seem clear but the explanation is obscure Boiled cow's milk appears to produce effects in the newborn baby's intestine which human milk cannot achieve It can scarcely be the direct introduction of living bacteria, and, if the seasonal variation now discovered by Salomonsen is considered, even dead bacteria are unlikely to be the explanation Does vitamin K or its precursor come into the story ? Is this present in cow's milk and is there a seasonal variation in the quantity ? Views on the boiling of cow's milk are unfortunately not so satisfactory in this country as in Scandinavia and it might prove dangerous to encourage the administration of cow's milk to infants in the early days of life here Until we know more it seems wiser to continue to treat the hæmorrhagic disease by injections of adult blood, promptly, on the earliest manifestation of the disorder Possibly there is a case for giving vitamin K to all mothers just before delivery as a prophylactic measure, this would be safer, on the whole, than giving of cow's milk to the baby But the method successfully adopted at the Rikshospital raises many points whose investigation may throw light on the still obscure pathogenesis of the hæmorrhagic disease of the newborn

THE FIRST PERMANENT MOLAR

DENTAL surgeons have lately been discussing the merits and demerits of extracting the first permanent molars as soon as they appear A A Wilkinson claims[1] that in 99% of mouths there is insufficient room for the teeth and that dental irregularities and the impaction of third molars are the result, if the first permanent molars are extracted as a routine, the evils of overcrowding disappear in every case, teeth drift into good alignment, the dental arches widen, caries is reduced and in 60–70% of cases entirely prevented, and, judging by observations continued over 25 years, pyorrhœa does not develop in later life He advocates removal before the roots of the second permanent molars are more than half developed, the best age usually being between 8 and 10½ years His illustrative cases all have satisfactory dentitions, but he publishes no models of the original conditions for comparison He is so emphatic that he should have presented more detailed evidence, in order to allay criticism Conclusions from independent workers would be valuable, but it is doubtful whether others are working along the same lines Statistics of the incidence of caries after the extractions would be specially useful, for though it is reasonable to suppose that interstitial caries might be reduced it is hard to see why there should be a reduction in occlusal caries It is widely agreed that these four molars ought to be extracted in some cases, but it seems a doubtful claim that every mouth would benefit Where the deciduous molars have been removed early, and the drifting of the remaining teeth has encroached on the space for the future premolars, it may be necessary to remove the four molars in order to prevent irregularities Similarly their extraction may prevent crowding where the jaws are unusually small The irregularities arising from these two causes, however, are seldom severe enough to require extraction of the four largest teeth, and choice should fall rather on the premolars, which are not so wide and which have the advantage of providing space near the front of the mouth where it is readily available for the incisors and canines The first permanent molars are more prone to decay than other teeth, and in cases where it is doubtful whether they will last until adult life it may be as well to remove them at a time when the spaces will tend to close up The fate of individual teeth cannot be decided purely on their own merits, the equilibrium between the two jaws must be considered Extraction of lower teeth may call for a reduction of teeth in the upper jaw, though loss of upper teeth does not necessarily call for compensating lower extractions Sometimes the removal of the first permanent molars may lead to excessive overlap of the upper and lower incisors, a condition unfavourable to the health of the incisors in middle life, sometimes the vertical position of the upper incisors is not maintained, and the natural fullness in the lip contour gives way to a shrunken appearance, sometimes spaces persist which are small enough to allow food to lodge between the teeth and cause discomfort and not large enough to permit the tongue to clear them easily In other cases the crowns of the lower second molars may tilt forward, forming a stagnant triangular area between themselves and the tooth in front, and this leads to local lesions of the periodontal membrane The second premolar commonly travels backwards, leaving a considerable space in front of it, in the region where the effort of mastication may be most concentrated Veterans can remember a similar vogue for removing the first permanent molar thirty years ago Today we may doubt

THE PREVALENT DISEASES OF LIBYA

By Philip Manson-Bahr C M G , D S O , M D Camb , F R C P
SENIOR PHYSICIAN TO THE HOSPITAL FOR TROPICAL DISEASES, LONDON

Information on the nosology of Libya is difficult to obtain Such reports as exist, emanating from Italian sources, are scanty and sketchy, and are often derived from hearsay evidence Thus, the medical survey of this region in the ambitious work by Croveri, "Patologia Tropicale, Subtropicale e Parassitaria" (1935) is marred by the fact that the material appears to be culled from existing works on tropical medicine, rather than from personal observations, and is mainly remarkable for the bombastic foreword by the Duce himself on the political aspects of this region The epidemiology conforms to that of the North African coast and the diseases are similar to those of the contiguous Western Desert boundaries of Egypt with which I became familiar during the campaigns of 25 years ago

The colony of Libya (or Tripoli) is of considerable extent and covers an area of approximately 900,000 square kilometres The greater southern portion is composed of bleak unfertile desert (Libya proper); the northern of a rugged more fertile coastline, embracing small towns and cultivated patches with many historic associations and generally known as Cyrenaica and Tripolitania This coastal zone, being exposed to the maritime breezes, has a more salubrious and temperate climate, being blessed with a more abundant rainfall, than the torrid, arid interior The Italian colonists have divided the colony climatically into graduated zones—the maritime, steppe, subalpine, semi-desert and desert proper The rainfall is sporadic, limited to the months of October to March with a maximum intensity in December

MALARIA

Although benign tertian and quartan malaria are reported from the coastal region, it is the subtertian (*Plasmodium falciparum*) which is the most widespread and feared in the Southern desert (Fezzan) and, as in similar situations in Egypt and Algeria, a virulent type is met with in palm-fringed oases which under war conditions assumes most puzzling and protean forms, so much so that its true nature is often not suspected by the unwary From experience gained in the last war it appears that the most virulent forms occur most frequently in the cold season, as at the present time, and are conveyed by hibernating mosquitoes The main anopheline carriers are *Anopheles multicolor*, which breeds in salt water, and *A sergenti* which breeds in fresh (Kirkpatrick 1925), so that the former is more likely to be prevalent in the coastal districts and in brackish water in the interior

Subtertian malaria may manifest itself under such circumstances by prolonged typhoid-like pyrexia Splenomegaly, which is commonly stressed in textbooks, in primary affections is not always evident in these cases The algid cases, which form a high proportion, may assume an abdominal complexion, often associated with diarrhœa and dysenteriform symptoms and with intestinal disturbances, suggesting an abdominal complication, so that their true malarial nature may be overlooked The clinical signs may be confined to the hepatic region, simulating cholecystitis, or to the right iliac fossa suggesting appendicitis Surgeons especially should beware of these abdominal pitfalls and not be tempted to operate without ample microscopical investigation of the blood The cerebral forms may be comatose or epileptiform, and if hyperpyrexia is present may be mistaken, as they often are, for sunstroke or heatstroke Cerebral involvement may simulate mental disturbance, such as mania, or even alcoholism Cardiac and pulmonary forms have also been met with under war conditions In fact there is no limit to the clinical disguises which this type of malaria may assume

It is necessary to emphasise the value of intramuscular or intravenous injections of quinine dihydrochloride in these severe cases None of the newer antimalaria drugs can compete in efficacy with that of quinine in these emergencies, although Atebrin (mepacrine hydrochloride) is undoubtedly beneficial in the less severe cases This drug acts best in conjunction with moderate quinine therapy Blackwater fever as a sequel to subtertian malaria may be occasionally met with in the southern desert of Fezzan

Although subtertian malaria holds pride of place, yet benign tertian, on account of its persistency and liability to relapse, constitutes a severe military handicap It is in this infection that a combination of Plasmoquine (pamaquin or Præquine) and quinine is most effective in preventing relapses Quartan malaria from the military viewpoint is negligible

LEISHMANIASIS

Visceral leishmaniasis or kala-azar, occurs sporadically along the whole Mediterranean coastline When it turns up it is a medical curiosity, but it should be borne in mind that it is there Mediterranean kala-azar is mainly found in children and the strain of parasite is designated *Leishmania infantum*, it is probably conveyed by the bite of a sandfly *Phlebotomus perniciosus* A similar indigenous infection is found in the local dogs and is known as *L canium* The close association with the human disease is probably more than fortuitous

The easiest and most practical method of establishing diagnosis is by gland puncture It has only recently been discovered that in kala-azar there is a generalised adenitis and that the inguinal lymph-glands are almost invariably enlarged I have confirmed this in the last seven cases investigated, and, following the method of Kirk and Sati (1940) have been able to demonstrate Leishman-Donovan bodies in preparations made by gland puncture This is a simple procedure The gland is pinched between the finger and thumb and a dry sterile hypodermic needle (No 16) is inserted into it By massaging the gland, the lymph is forced into the lumen of the needle; by affixing the barrel of the syringe it is blown on to a slide then dried, stained with Leishman's stain, and examined

According to Adler and other authorities, the North African kala-azar is more resistant to antimony treatment than are Indian cases, but Adams and Yorke (1939) have recently introduced a new compound, 4 4' diamidino-stilbene, which has been tried out in Palestine by Adler and Rachmilewitz (1939) with eminently satisfactory results It is administered by the intravenous route, 360 mg being given within seven days

Cutaneous leishmaniasis, or oriental sore, occurs sporadically along the whole North African coast, beginning as a papule on the face hands or other exposed parts of the body It breaks down into an ulcer of highly characteristic appearance The diagnosis is usually easily made in the early stages and *Leishmania tropica* can be identified in the serum obtained from the edges of the sore by puncture with a hypodermic needle These sores spread in a chain manner via the lymphatics where they cause nodules to form and in which leishmania bodies may often be demonstrated This disease is also conveyed by a sandfly, the carrier being *Phlebotomus papatasii* A great number of remedies have been advocated In multiple sores intravenous antimony therapy seems to be effective. In localised individual lesions a cignolin paint seems to be most satisfactory The formula I advocate is as follows —

℞ Cignolin	gr 4
Ichthyol	gr 8
Ol cadini	♏ 40
Benzoli rect	ad ℥i

Fiat pigmentum To be applied to the sore daily for 14 days

RELAPSING FEVER

Relapsing fever is a common North African disease and is of two types There is the universally louse-borne infection which is prevalent amongst the Bedouin Arabs, especially during the winter months when they lie huddled together and swathed in not over-clean blankets, and which under these conditions is commonly associated with typhus Then there is the tick-conveyed form, the organism of which Croveri asserts is identical with *Spirochæta duttoni* from Central Africa Much more probable it is the strain known as *Spirochæta hispanica* which is conveyed by a soft tick—*Ornithodorus marocanus*

The albumin-globulin ratio remains as a rule the same in serous fluids as in the blood, but it is commonly found reversed in cirrhotic fluids The rarer types of fluids, such as chylous, mucinous and cholesterol, are associated with fewer primary conditions, but Paddock found chylous fluids from 5 patients with cirrhosis, 3 with neoplasm, 2 with nephrosis and 1 with subacute bacterial endocarditis Mucinous effusions are apparently always associated with some malignant growth in the abdomen

LEUKOPLAKIA AND KRAUROSIS

THE term leukoplakia vulvæ, in itself so specific and descriptive, has been loosely employed by gynæcologists to describe any condition of the vulva accompanied by white sodden and hyperkeratotic epithelium Dermatologists have for some time been pleading for a restriction of the term to its proper place and Agnes Savill[1] has attempted an exacter definition of what constitutes leukoplakia and kraurosis She divides leukoplakia vulvæ into three categories The first is false leukoplakia, really a lichenification of the vulva, due to prolonged irritation from scratching induced by pruritus, the normal skin grooves become exaggerated and the skin resembles grained leather, the colour of the skin surface is normal, pale or grey and covered with fine scales This condition resembles that described by Victor Bonney[2] as lipidosis vulvæ *It is never a precancerous condition* and removal of the cause of the scratching results in permanent cure The next important division of so-called leukoplakia is leukoplakic vulvitis Bonney defines this as an inflammatory condition with simultaneous changes in the epidermis and underlying connective tissue, both labia, clitoris, prepuce, posterior commissure, and, later, perinæum and anus are affected, but never the vestibule or the skin of the mons In the first phase the affected parts are red and swollen, in the second the labia are white, thickened and retracted, histologically this phase shows epithelial hypertrophy, elongation of the interpapillary processes, lymphocytic infiltration and disappearance of the elastic fibres in the upper part of the dermis with an increase in the deeper part In the third phase there is dense whiteness with red fissures, and the labia become flattened out In the final phase connective-tissue sclerosis is complete, the affected area is smooth and shiny, and the elevations of the labia and clitoris are almost ironed out There is no longer any pruritus This is a precancerous lesion The end-result may be a contracted introitus that closely resembles that left by senile kraurosis The third division, true leukoplakia resembling that seen on the tongue, is very rare[1] The importance of Savill's classification lies in the segregation of leukoplakic vulvitis from simple lichenification of the vulva The treatment of leukoplakic vulvitis may well be radical surgery on account of its precancerous reputation, while that of lichenification of the vulva can never be The term kraurosis should be reserved for a progressive sclerosing atrophy of the mucocutaneous coverings of the vulva, leading in time to a stenosis of the vaginal introitus and an obliteration of the prominence of labia and clitoris The mucous membrane is smooth, dry and shiny, the colour is white, yellow, red or spotted Often there are small telangiectatic spots especially around the urethral orifice, giving the appearance of a carbuncle, though falsely According to Savill kraurosis may be caused by involution of the ovaries produced by surgery or old age, or it may be associated with a recurrent infective dermatitis The second type affects much younger patients in whom the ovarian function is as yet unimpaired, the pathology seems to be exactly similar to that of the later phases of leukoplakic vulvitis The pendulum has swung back to the opinion of the gynæcologists that leukoplakia and kraurosis are—with reservations—one and the same disease There is much of interest in Savill's paper, but we cannot agree that the proper treatment of senile kraurosis is electrotherapy, when hormone treatment properly exhibited in suitable dosage has given such uniformly excellent results

SEX AND AGE DIFFERENCES IN TUBERCULOSIS

THE relatively high rate of mortality of young adult females from respiratory tuberculosis and its reluctance to decline in recent years are well-known features of this disease Reliable statistics of its incidence in the two sexes and at different ages are more difficult to come by and of interest, therefore, is a study recently made by Prof R M F Picken of the data published in the annual reports of the Welsh National Memorial Association[1] In the four years 1936–39 a total of more than 9000 new cases were reported, of which approximately 5000 were males and 4300 females In the first years of life, 0–14, there is no sex difference in incidence The populations at risk differ but little and there were 334 male and 343 female patients *In young adult life, 15–24, on the* other hand, there is a distinct excess of female cases, 1760 to 1403 males, although at these ages the female population is rather smaller than the male At ages 25–34 there is again little difference between the numbers at risk, and the incidence is also of the same order with *1123 male and 1205* female cases *After age 35 there* appears a pronounced excess of males—2180 males to 991 females—the populations at risk being approximately the same Further analysis shows that in the young adult group, 15–24 years, 53% of the females were Tb + in the sputum against 49% of the males, and 37% of the former were classified as clinical group *3* (advanced cases) against 30% of the latter In other words not only do a much larger proportion of new cases occur at young ages in females but also at these ages the prognosis is less favourable, as measured by the presence of tubercle bacilli in the sputum or the clinical stage to which the disease has progressed Although the data do not permit the calculation of real fatality-rates they suggest that, once contracted, respiratory tuberculosis is a disease of more serious prognostic import among females at practically any age and especially in young adult life Such observations from statistics accord with clinical experience, they cannot help us to explain these fundamental sex differences in the behaviour of the disease Are young women, for instance, Professor Picken asks, more exposed to massive infection in the home? Or is their special susceptibility entirely physiological? The answer, he suggests, must come from tuberculosis departments through a combination of clinical and pathological observations with social inquiry

THE Royal College of Physicians have appointed as their delegates to the B M A Medical Planning Commission Sir Charles Wilson, London, Dr H L Tidy, London, Prof J A Ryle, Cambridge, and Prof H P Himsworth, London The Royal College of Surgeons have completed their quota of delegates by the appointment of Mr A Wilfrid Adams, Bristol, and Mr John Hunter, London

THE Vice Chancellor of the University of Oxford has issued a statement, which has the authority of the Minister of Labour and National Service, saying that the reservation of medical students is unaffected by the proclamation of Jan 29, and that the extension of the reservation to all medical students is being considered

SUBSCRIPTION OFFER TO STUDENTS —The proprietors regret that owing to the present difficulties and heavy additions to cost they are reluctantly compelled to increase the students' subscription to THE LANCET from *10s 6d* to 1 guinea per annum as from 22 February, 1941

Africa. It is more likely to be non-venereal syphilis known throughout the African desert el This appears to be a mild form of syphilis attenuated a strain that it fails to reproduce ajor features of the disease as it manifests itself in eans In many instances the primary infection quired by contact and not by the genital route complications are apparently extremely rare and eadily amenable, as is yaws, to salvarsan therapy erating granuloma that particularly loathsome eally conveyed disease, with its peculiar features ethod of spread, is much to be dreaded in this part rica It is necessary that it should be detected when it is amenable to antimony therapy mphogranuloma inguinale or climatic bubo, is most universal infection among the native inhabit-

The main thing is to recognise the characteristic es The causal agent an ultramicroscopic virus, enable to sulphanilamide treatment

SORES AND ULCERS

e septic sore, or veld sore, is primarily a disease of the t and occurs on the knees, hands and other exposed rts of the body. Many of these sores are due to a htheritic infection of the skin as originally described Craig (1919) in the Sinai Desert They run a special ical course beginning with a vesicle (fig 1), usually nd a hair follicle and at the site of some previous ury, this bursts and forms a shallow ulcer which is tely painful A chronic punched-out ulcer with dermined edges results and may persist over a very g time (fig 2) In a proportion of cases diphtheritic ralysis may ensue, either of the iris, hands or feet, d, not infrequently the sores are associated with ucial diphtheria They are found mostly in cavalry its, in the camel corps, and to a less extent in the fantry and mechanised units They respond readily to tidiphtheritic serum Already a large number have en reported from the Middle East and are identical appearance with those seen 25 years ago Diphtheritic res have lately been found on horses, and this may be source of the human infection There are other kinds septic sores which may develop at the site of any nall scratch or abrasion

2—Desert sore Chronic punched-out stage Diphtheria bacilli isolated by culture.

The true tropical ulcer or sloughing phagadena is ommonly seen in underfed natives The ulcer, which is sually on the legs, is larger and deeper than the septic re, and is rapidly spreading and extremely destructive the underlying tissues The best and most practical ethod of treatment is by elastic plaster bandages

SCORPIONS, VENOMOUS INSECTS AND SNAKES

The Libyan desert is a land of pests and may be terally said to "rain scorpions" Seventeen species are sted by Zavattari (see Medulla 1937) The most angerous is *Prionurus australis*, especially during the ot season, when its sting has sometimes proved fatal to children and old people (Sergent 1938) The chief symptom of the sting is a burning pain radiating from the part The sting itself is often so small that it is very hard to detect Profuse salivation is usual The treatment is almost entirely symptomatic, but in severe cases anti-scorpion serum may be injected.

Venomous snakes include *Naja haje* the African cobra, and among the vipers are three species—*Cerastes cornutus* the horned-viper, which is specially deadly and perfectly camouflaged by its markings *Cerastes vipera* and *Echis carinatus*. the Indian "phoorsa"

Finally there is the black-widow spider *Latrodectus* (fig 3) commonly distributed throughout this area The species is probably *L lugubris* There are conflicting accounts regarding the severity of the effects of the bite of this insect, but the main feature is that occasionally it produces the appearance of an acute abdomen, with board-like rigidity and great tenderness The main point is to recognise that this is a toxic phenomenon and not to operate The toxin of the poison glands is a powerful hæmolysin, causing œdema and inflammation at the site of injection and sometimes an urticarial rash

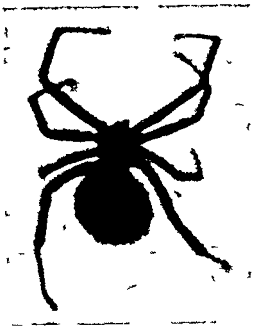

FIG 3—Black-widow spider, *Latrodectus lugubris*

I am indebted to the director and staff of the Bureau of Hygiene and Tropical Diseases for procuring references of local interest, and to Captain Manton, Army Dental Corps, for the photographs, which were taken in Palestine during this campaign

A CONFERENCE ON A.R.P.

WHEN the Government, in those distant days before Munich, came to consider plans for A R P. they had to parcel the country into administrative areas and they decided to divide it into a number of civil defence regions too large to deal with the detail of planning It still remained to be decided which areas should be given the local autonomy of a scheme-making authority The Government chose county councils, the county boroughs, city councils and the metropolitan borough councils to be the authorities for this purpose This decision, apart from giving an added impetus to machinery which many had in the past declared to be outworn and apart from its perpetuation of boundaries formed by the union of 19th century vestries and the barter of properties in the Middle Ages, also gave to these local authorities the chance to justify their existence by the execution of a task bigger than any they had hitherto undertaken It is fair to say that the manner in which the scheme-making authority deals with its civil-defence responsibilities will constitute its claim or otherwise to survival in the reconstruction which will follow the war The administration of casualty services is not the least part of such an authority's responsibilities and many a man in general practice is now making his first contact with local government through his work in first-aid posts and mobile units We in the medical profession know only too well the contradictions and the difficulties—some of local some of central origin—which are involved in this work

On Feb 2 a conference was jointly held in Islington Central Library to which authorities in the London or *erraticus* The remedy for these fevers is, of course, intravenous injections of Neosalvarsan It may well be that the animal reservoir-host of this spirochæte is the desert rodent (*Ctenodactylus gondi*) known as the " gondi rat "

The Italians mention *sodoku*, or rat-bite fever, which is said to be found locally, but this is a universally distributed disease caused by a minute spirochæte *Spirillum minus*, and the reservoir-hosts are rats, mice and cats, by which it is conveyed to man through the bite Here again Salvarsan is the remedy

TYPHUS

Typhus is an Arab disease The epidemic form, louse conveyed, is prevalent among the Bedouins during the winter months The rash is often difficult, if not impossible, to distinguish on the dark skins, but may be made more evident on the arm by compression of the brachial vein The sequelæ of typhus among these nomads may often be more terrible than the fever itself Then there is the tick-conveyed " fièvre boutonneuse " The tick concerned is *Rhipicephalus sanguineus*, the common dog tick, and this animal is considered to be the reservoir-host of the virus A distinctive feature is the appearance of a primary sore at the site of the infecting bite which may subsequently become gangrenous and is known as the " tache noire " Lymphangitis subsequently develops The cause of this fever and the rash it produces are very similar to those of the louse-borne disease The diagnosis of typhus fever has been placed on a more secure basis by the Weil-Felix reaction, in cases of typhus the serum agglutinates emulsions of *Bacillus proteus* X 19 to high dilutions This proved of great assistance in diagnosis during the last war, especially in the louse-conveyed disease This reaction is not, however, found in fièvre boutonneuse and there appears to be some doubt whether serum from patients with this disease gives a reaction with the allied strain *B proteus* X K

SANDFLY FEVER AND DENGUE FEVER

These are two North African insect-borne fevers which are quite distinctive and may be of considerable military importance in the warmer months, especially towards autumn when the insects which convey them abound In the former the carrier is the sandfly, *Phlebotomus papatasii*, and in the latter the domestic mosquito, *Aedes aegypti* Both diseases are due to a virus which undergoes a course of development in the body cavity of these insects

Sandfly fever is of short duration, lasting as a rule from three to four days There are few distinctive signs apart from the injected conjunctiva which gives to the facies a bloodhound-like appearance which has given rise to the popular name " dog-faced fever " It is now thought that the virus is conveyed from one generation of the sandfly to the next by the habit of the larvæ of feeding on the decomposing carcasses of their progenitors which contain the essential cause of the disease

Dengue fever lasts from seven to ten days and culminates, in the majority of cases, in the characteristic dengue rash, described as being half way between measles and scarlet fever The bone pains of this fever are quite characteristic and the patient usually feels more ill than he really is In both these trivial fevers it is the disability during convalescence which constitutes their most serious influence on military effort

DIETETIC DISEASES

Of the dietetic diseases pellagra is most often seen in the aborigines of Libya It is essentially a malady of the underfed peasant farmer, and is not likely to be encountered, as it was in the last war, in British troops The causative diet is one deficient in protein, and it has been conclusively proved by Spies and his colleagues that lack of the P P factor (nicotinic acid) is the basal cause The mainstay in the diagnosis of pellagra is the triad diarrhœa, dermatitis and dementia Beri-beri is also a war disease of this region and manifests itself usually in the dry paralytic form Under modern conditions it is easily curable by injections of vitamin B_1 (aneurine or thiamin)

DYSENTERY

The dysenteries are war diseases par excellence In Libya, as in other parts of Africa, the bacillary form predominates, and this acute and often fatal disease is mostly to be feared in desert warfare The infection seems to be conveyed by the house-fly, *Musca domestica*, which swarms in this region It is to be hoped that lessons learned in the desert campaigns of the last war will not be overlooked in this—that bacillary dysentery (Shiga, Flexner and Schmitz infections) will be readily recognised and promptly dealt with by well accredited remedies The chief danger is that it may be mistaken for amœbic dysentery and emetine injections given to the detriment of the patient The main modern development in the treatment of acute bacillary dysentery is the recognition of the value of transfusions of blood, plasma, or even reconstituted plasma, in overcoming the dehydration and preventing collapse Anti-dysentery serum (anti-shiga serum) is of special value in Shiga infections Targesin, a complex colloidal combination of albumin with a diacetyl tannic acid silver salt, has been well spoken of The dose is two tablets by the mouth three times a day Moro's apple diet as a remedy against uncontrollable diarrhœa is also to be noted The explosive desert diarrhœas known as " gippy tummy " are probably manifestations of infection with Sonne's bacillus Such conditions are apt to be extremely disagreeable, as well as debilitating

Amœbic dysentery is a long drawn out and wearying disease which may assume a great variety of clinical forms and is seldom either very acute or fatal This infection, which is undoubtedly water-borne, is widely spread through the cultivated coastal districts Exact figures are difficult to obtain Grixoni has stated that *Entamœba histolytica* cysts occur in 1 8% of the Libyans, which seems a low figure compared with Egypt Similarly the assertion of Corradi that this protozoan accounts for 82% of clinical cases is probably an exaggeration. It will more likely be found that amœbiasis accounts for 7–10% of the cases of " clinical dysentery " The importance of eradicating amœbic infection from the intestinal canal with emetine bismuth iodide cannot be overstressed

HELMINTHIC DISEASES

Ankylostomiasis is said to be prevalent, its extent is unknown, but is probably comparable with that which obtains in Egypt among the native Libyans From experiences gained in the last war it is improbable that it will spread to the Imperial troops *Tænia saginata*, the beef tapeworm, is said to be common and arises from eating the beef of native cattle and possibly camel meat as well Ascaris and threadworm are prevalent, and attention may be drawn to the simple method of treatment with phenothiazine in doses of 4–8 g daily for 5–7 days (Manson-Bahr 1940)

Bilharziasis is also widespread throughout North Africa The urinary form *Bilharzia hæmatobia* occurs in the desert oases, especially in the Southern districts of Fezzan and Ghat The intermediary host is, as in Egypt, the snail *Bullinus contortus* In some districts, according to Zavattari (1934), 60–80% of boys and 15–20% of adults are infected The intestinal form, *B mansoni*, has also been found (Cicchito 1938), and the intermediary host appears to be *Planorbis pfeifferi* which is especially numerous in the oasis of Ghat

VENEREAL DISEASES

Croveri says that yaws is prevalent in Arabs, but it is improbable that it is the same disease as is present in Central and

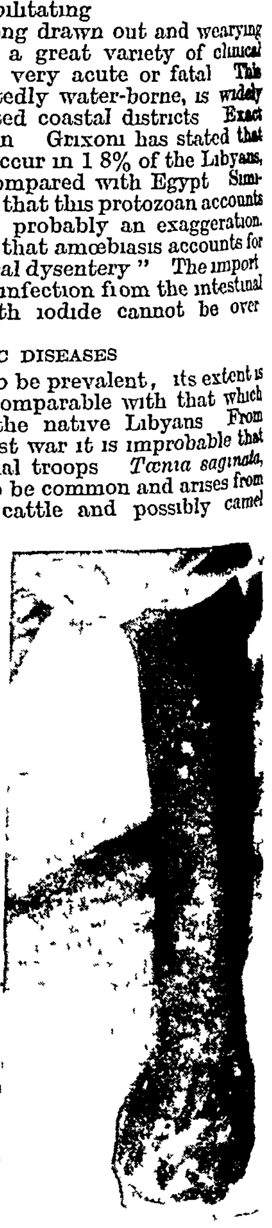

FIG 1—Desert sore Early vesicular stage Diphtheria bacilli isolated by culture

In England Now

A Running Commentary by Peripatetic Correspondents

I AM one of those who believe that soldiers should be in roper soldiers' hospitals under the care of soldiers' octors, but I am not frightened by your insistence (Feb , p 149) that in these hard times everyone should share he base hospitals Excepting in so far as his characters re the same as those of all good doctors (not necessarily he same as good physicians or surgeons) the soldiers' octor is least needed at the base hospital—more in the nit, battalion of infantry or brigade of artillery, and most n the field ambulance, where the C O needs to be a tough ut to avoid his brigade group crumbling away from nnecessary illness Once it is decided the soldier must o down the line his doctor's special characteristics isappear, to reappear in the convalescent hospital or amp In the base hospital he is only needed to prevent he hospitalisation of men (and women and children) hich results from keeping them in unduly long or keepng cases that never should be there The convalescent amp is a hospital, not a training depot where hardening f the fit man is done Hardening of the not yet fit man ay be begun in convalescence , but give them a chance nd the military authorities will expect the convalescent amp to turn out hardened soldiers as well as recovered nvalids If it gets that reputation, M O s will refuse to end out cases and will obstruct seniors when they try o do so Then hospitalisation starts The convalescent amp must therefore remain a medical unit I wonder hether it can take civilians as well as members of the Forces The latter are under military law, and the ormer are not Military law is out of place in the onvalescent stage , but it may be useful in the background Toughness combined with kindness of heart—nd no doctor is any good without both—can do the job without the help of the C O s orderly-room If I am ight, and it is not just an old man's dream, convalescent camps should take civilians (men and women) as well as he men and women of the Forces and treat them all ogether The Pendragons have shown how to make such a dream come true And why does the convalescent camp matter ? Just because base hospitals get cluttered up with men that should not be there , they are not fit for full duty, but they ought not to be in hospital

* * *

The latest edict on a triple ration of fat and meat for diabetics is altogether incomprehensible to my mere medical mind A little mental arithmetic shows that it provides for approximately 135 g (or 1220 Calories) of fat and 60 g (or 240 Calories) of meat daily Most of us who are interested in diabetes are now of the opinion that with a high carbohydrate diet of 200–300 g daily the amount of fat should be reasonably restricted and 100 g daily is about the highest level to which the fat in the diet should rise Why, therefore, the diabetics of the country should be granted such a medically unjustifiably large ration when the children (not to mention the non-diabetic element who are also doing their best to play their part in the defence of their homes) are rationed to the bare minimum of fat compatible with health is one of these problems which, while a headstrong government department may consider it settled once and for all, the medical profession ought to assail with all its power Is it a question of the vested interests of diabetics—always rather a pampered section of the community—or is it an example of our stupid national habit of sentimentalising over the unhealthy to the extent of victimising the healthy ? But, perhaps it is only Whitehall bungling again I have been glancing over the instructions which we issue to our diabetic patients, and for the life of me I can find no reason why they should have any more than a double ration of meat

Professor Mottram's recent letter (*Lancet*, Feb 1, p 159) voices a fear which has been growing in the minds of many of us Article after article of food which the Ministry of Food urged us to eat has disappeared from the shops Cheese was the epitome of all that a foodstuff should be , with cheese as a staple article of food our diet would be satisfactory Those of us who had long believed in the excellence of the traditional English bread, cheese and beer chortled with pleasure, and non-cheese-eaters soon learned the advantages of the habit , but the next thing we find is that cheese has become a rarity only to be obtained if our unfortunate wives pay repeated visits to the grocer To the non-politician cheese seems to be the ideal food for storage purposes, and with the tremendous output of our Dominions available the neglect to lay in adequate amounts of it either before or during the early days of the war seems to be verging on either laxity or criminality Again, there is the latest example of all—oatmeal—announced on the wireless and in the press as *the* food for war-time , and in less than a week not a grain is to be obtained in the shops Why on earth do foodstuffs disappear from the shops the moment their price is controlled (e g onions, poultry, and rabbits), why is food such as meat allowed to rot in the shops until it has to be thrown out as unfit even for pigs, and why are artists appointed regional directors of the meat trade while fully qualified and experienced butchers are sent into the Army to act as infantrymen or clerks ? Doctors are notoriously bad administrators or one would pray for the appointment of a medical food dictator

* * *

There seems to be an all-round drop in the sense of personal responsibility nowadays So much is done for us that we can, if we like, carry on with very little initiative if our ambitions are modest The professional man, depending as he does on his own efforts, has as a rule a well-developed sense of responsibility , the artisan in war-time need have almost none But the professional man can, if he chooses, avail himself of many of the aids which are dangled before the artisan He can send his children to the council school, he can let them take their chances in the examinations for scholarships at the grammar school and university That he does not is his own affair In his actual profession, however, it is not so easy There he must stand on his own feet, must fight with his own hands, unless he chooses to take a state-paid job If he does that, and is content to go with the swim, he need exercise very little personal responsibility His wage will be paid regularly and will increase according to scale He is certain as anyone can be that, well before he is past enjoying it, he will be able to retire on a pension A good many of us must be regarding him with envy today—those of us who are faced with a rapidly declining income, rising taxation, an ever-increasing cost of living In the wage-earning class the average man, woman and young person of today can and does earn a comparatively large wage with little addition to his or her responsibilities The cost of commodities is bigger than it was and is growing, but they are not in plentiful supply, the artisan can and must spend little more than he did on them His rent is not increased as a rule He has no growing school bills to pay He gets his ordinary doctoring through the panel, treatment at the hospital, if he needs it, through a contributory scheme If sick he gets a weekly money allowance from the state insurance, supplemented, if he has made provision, by his friendly or trade society Take it by and long he has little to fear but the loss of his job or a long illness Society has been so organised that his responsibilities have been reduced to a minimum But—and it is a very big but—the war will not last for ever Sooner or later there will come a time when highly paid employment will become not a thing to pick and choose but a thing of the past Then the artisan will find he has responsibilities in bucketfuls So, for that matter, will everyone else

For the moment, however, we are considering things as they are Is well paid, easily obtained, employment a good thing *in itself*? In some ways it is, but not in all It used to be axiomatic that nothing was worth having that did not have to be striven for, and on the whole that is true Today, if works welfare workers and such like are to be believed, some of the younger artisans are becoming increasingly difficult Disputes concerning wages and conditions of employment are increasing, and that often in the best equipped workshops While the older men go on with their work some of the younger ones are ready to down tools with little provocation They know that they can get another job without difficulty This, let it be stressed, is true only of a small minority The great majority are content to carry on, big wage or no big wage, because they know they are needed The spirit of region which administer a civil-defence scheme were invited It was attended by representatives from about half of the authorities of that region, who all explained that they attended in their personal capacity and were in no way mandated by their authorities to express their view The administrative side had a fair representation, there being apart from councillors and engineers some eight medical officers of health and a few members of the E M S The two bodies which combined to call the conference were the Association of Architects, Surveyors and Technical Assistants and the A R P Coordinating Committee, with which Prof J B S Haldane and Prof J R Marrack are closely associated

THE SHELTERS

Medical men are prepared to recognise in an increasing degree that their responsibilities extend beyond the mere treatment of such disease as is brought to their notice by the sufferer himself Today public health is no longer the monopoly of doctors employed by the central ministry and the local governments—indeed, it is these doctors who are the first to stress the fact Today also the general public are being subjected in an increasing degree to new strain all tending towards a general lowering of health standards Dr JOAN MCMICHAEL, starting from this common base-line, addressed the conference on the medical aspects of A R P and quoted from a speech by Mr Malcolm MacDonald in which he commented on the very real dangers to the public health arising from a "degree of overcrowding literally appalling" In support of this Dr McMichael gave the standard minimum figures per occupant which the Public Health Acts allow

Hospitals	1000 cu ft per head
Army barracks	600 " " " "
Canal boats	60 " " " "
" " (children under 14)	40 " " " "

She remarked that these figures read somewhat curiously alongside the report of the Horder Committee "Whenever possible the standard the Ministry of Home Security is at present advising—viz , 50 cu ft per person for indirectly ventilated shelters—might be followed until the present position of overcrowding is eased" As Dr McMichael commented, the population in London which cares to shelter must do so in conditions inferior to those obtaining in a canal boat Dr McMichael, in stressing the reality of the danger, quoted figures for the incidence of cerebrospinal fever 1938, 1288, 1940 (up to Dec 5), 12,500

The general feeling of those present was that the structural and medical problems involved in the provision of shelter were so intermingled as to have become inseparable About this there can be little dispute, though there was considerable argument concerning the official attitude to problems of shelter hygiene, at any rate in so far as planning is concerned As one delegate put it, "The policy of installing medical and nursing staff in shelters without even attempting to remedy structural hygienic faults is a policy of waiting for the worst To provide at the same time bad shelters with efficient medical aid is like throwing banana-skins on to a rush-hour pavement and handing out splints five yards further down"

The general tone of the discussion was extremely critical of the Government's A R P policy It was chiefly the Ministry of Home Security that suffered as being the department responsible for the primary design of the shelters The opinion of the conference was plainly to the effect that no-one could make a sound job of caring for shelterers under the conditions in which the ministry preferred to confine them

The cost per head of shelter accommodation decreases with a rise in the number of persons sharing it Such elementary amenities as water-closets and air conditioning plants have an alarming cost if this is spread over say twenty people , but expenditure falls to a practicable level if spread over several hundreds of users The Ministry of Home Security does not like large shelter units and all attempts to demonstrate the convenience and economy of the larger communal shelter have met with little sympathy Models were shown of large reinforced concrete shelters which have been popularised as "Haldane shelters" As Professor Haldane has pointed out, these shelters are based upon Mr Ove N Arup's designs which the Finsbury metropolitan borough coun adopted as reaching the required standard for a crowd area These shelters are really an aggregation of simi reinforced units so that a high degree of safety is achiev as well as a high level of "amenity" Actually safe rather than decreasing with grouping, considerab increases, since the honeycomb of reduplicated wa has an obvious cumulative effect in isolating the fo of an explosion

THE HOMELESS

One of the paradoxes of the blitz is the plight of th bombed out of their homes It is odd that the homel and the wounded are the two classes of our populati for whom shelter is provided only in the most exc tional circumstances Once in the converted L C school which serves as a rest centre the homeless ha usually to be content for their protection against bom with a fabric designed in the 19th century merely exclude the elements The Rev S EVANS of Plaist urged that those whose homes have been bombed in way deserved to be treated as paupers They w simply citizens deprived of their possessions by disast and who had been through a stiff ordeal As an instan of what not to do he related the history of eighty hum *beings in a rest centre of a county* borough on the E Side of London They were told to wait for a "bus take them to the country" One arrived and deposit them in a borough the other side of London Th they were sheltered in a common lodging-house for weeks and as no further attempt was made to deal wi them they drifted back into their bombed borough, or to crowd to a still greater extent the already ov crowded homes of their relatives It was too much, said, to expect a working-class housewife to search bombed district for alternative accommodation and the same time to look after a family The Governme had made the local authorities responsible for billeti and in view of the machinery at their disposal it shou prove, if resolutely tackled, one of the least diffic war-time tasks

The medical opinion present was against the use relatives' houses for billeting, on the ground that t average working-class house is usually overcrowded begin with A wider use of powers of requisition was adv cated , and it was pointed out that the local rate off always knew of empty premises as soon as they fell vaca

The conference felt very strongly the lack of dir contact with the regional commissioners and passed resolution demanding a right of representation regional headquarters It was pointed out that would benefit by this—the atmosphere at the top wou be less rarefied, local problems would be better met, a the public better served

It became obvious during the course of the day th whatever doctors themselves may think, the pub expects their interest and help in an ever-increasi degree and in an ever-widening field The war h brought to our large towns a new community life which no man can escape his responsibilities towards h fellows The doctor, from the nature of things, touch life at many points and the calls on him are correspon ingly greater Someone summed up one aspect of t medical situation in the phrase "Beat the germs well as the Germans" There are other things to be too, and in planning how they may be beaten it may well to reflect that rugged individualism and anarc are much the same thing—and that as a philosophy f victory anarchy is not to be commended

K W C S-L

As a war-time measure the Hospital for Sick Childr Great Ormond Street, with the cooperation of the Watfo Peace Memorial Hospital, is opening consultative outpati clinics at that hospital At first these clinics will be held o a week beginning on Friday, March 7 Medical and surgi cases should attend at 10 A M and ear, nose and throat ca at noon The clinics will be extended later if necessa They will be conducted by members of the visiting medi staff of the Hospital for Sick Children, and new cases must recommended by a doctor Appointments should be made by letter through the almoner to the Hospital for Sick Children Clinic, Watford Peace Memorial Hospital, Watford, Herts

Letters to the Editor

SULPHADIAZINE

SIR —Recently Roblin and his associates[1] have scribed the preparation of sulphadiazine (2-sulph-lamidopyrimidine) Feinstone and his collaborators[2] ve reported that the acute toxicity of sulphadiazine sed on blood concentrations of the drug was in the ghbourhood of from 175 to 200 mg per 100 c cm the L D 50 in mice Chronic toxicity studies on nkeys showed that sulphadiazine produced less tissue mage than did sulphathiazole or sulphapyridine, and e blood concentrations of the drug resulting from given ses of sulphadiazine in monkeys and in mice were out four times as high as those resulting from similar ses of sulphapyridine or sulphathiazole They noted at the drug existed in the blood primarily in the un-njugated form because its acetyl derivative appeared be readily excreted in the urine These observers ted that sulphadiazine had an excellent degree of erapeutic activity in experimental pneumococcal, emolytic streptococcal, staphylococcal, and Fried-nder's bacillary infections in mice

We have been able to confirm these observations In fections in mice, our experiments lead us to believe at sulphadiazine is approximately as active a thera-eutic agent as is sulphanilamide in streptococcal infec-ons In experimental pneumococcal infections in ese animals, sulphadiazine again proved to be about as ffective as sulphathiazole or sulphapyridine In experi-ental staphylococcal infections, sulphadiazine seemed be slightly superior to sulphathiazole as a therapeutic gent

In infections in mice produced by the intramuscular jections of *Clostridium welchii* or *Cl septique*, sulpha-iazine was highly effective when administered either y the oral or local route None of the drugs which we ave tested has proved very effective against *Cl edematiens* (*novyi*) infections in mice

Our studies on the absorption, distribution and excre-ion of sulphadiazine in man indicate that the drug is omewhat less rapidly absorbed from the gastro-intes-inal tract than is sulphanilamide, sulphapyridine or sulphathiazole In the blood, the ratio of the unconjugated and acetyl fractions of the drug is frequently less than that which has been previously noted for sulphanilamide Sulphadiazine is excreted less rapidly than is sulphanilamide or sulphapyridine if renal function is normal In the urine about a third of the drug exists in the acetylated or conjugated form The relatively small amounts of the conjugated fraction found in the blood seems to be due to the fact that acetyl sulphapyrimidine is readily excreted by the kidney The drug passes over into the spinal fluid in concentrations of one-half to four-fifths of those which exist in the blood

It is too early to pronounce on the clinical therapeutic effects of sulphadiazine, but to date our experience with this drug leads us to believe that it is about as effective as sulphapyridine or sulphathiazole in the treatment of pneumococcal pneumonia in human beings and of definite value in the treatment of hæmolytic streptococcal and staphylococcal infections in man In Friedländer's bacillary infections it has proved very effective

The interesting thing about this drug is that it has not in our experience (which now covers its administration to about 80 patients) produced any nausea or vomiting We have noted one instance of drug fever, one of drug rash, and one of conjunctival injection in this group of patients The drug does not produce a fall in the carbon-dioxide combining power of the plasma, nor have we witnessed any signs of renal injury up to the time of writing There have been to date no noticeable changes in the red-cell count or hæmoglobin of patients who have received this drug

It is very easy to obtain adequate concentrations of this drug in the blood, and we feel that in the acute phase of lobar pneumonia a concentration of sulphadiazine of from 7 to 10 mg per 100 c cm should be maintained It has been our custom to prescribe an initial dose of 4 grammes of sulphadiazine, to be followed at six-hour intervals by 1 g of the drug; then 1 g should be administered every six hours until the temperature has been normal for three days

If the initial promise of high therapeutic effectiveness and low clinical toxicity of this drug is borne out by more extensive experience, it means that sulphadiazine will be a most welcome addition to the sulphonamide group of chemotherapeutic agents PERRIN H LONG

The Johns Hopkins Medical School, Baltimore, Maryland

ARTIFICIAL SHORTAGE OF DOCTORS

SIR,—With reference to your leading article of Feb 1 on the artificial shortage of doctors, I would ask you to correct a statement regarding orthopædic centres in the Army, which is not in accordance with the facts It is stated in this article that " the Army has 12 orthopædic centres in addition to those of the E M S, with their own establishments to maintain " The facts are that a number of surgeons with orthopædic training and experience have been authorised for certain military hospitals at home These hospitals will be regarded as possessing orthopædic sections (not centres) and are supplementary to the E M S orthopædic centres It is not intended that cases requiring highly specialised reconstructive surgical treatment, or whose return to military duty is doubtful, should be treated in military hospitals These are to be transferred to E M S orthopædic centres as early as possible The Army are not calling for occupational therapists and rehabilitation experts from civilian sources J M WEDDELL,

War Office, S W 1 Colonel Consulting Surgeon to the Army

SIR,—In reception areas, where the population has recently increased by 50–100%, doctors are still being removed and commissioned in the R A M C —a sentence to boredom, censoring, deciphering, &c Surely evacuees and the normal civil population deserve more consideration than this It seems that a request for exemption is likely to be granted until the end of this winter only —which to my mind is a very short-sighted policy

It is up to everyone to serve the country to the best of his ability, and it would appear absurd to join the R A M C where (to quote a phrase from Mr Handfield-Jones's letter) " there are lots of us here and nothing to do " rather than to stay in general practice where there is an increasing amount of work to do and an ever-decreasing number of doctors to do it Is it not time that this should be rectified before the general practitioners' work becomes too great and the civil population suffers ?

Gt Berkhamsted Herts C CARTER SHAW

SIR —I agree with you that pooling of the supply of doctors is necessary, and I would suggest (1) that all medical men more than three years qualified should be called up by age-groups to the age of 50 and placed in that pool so as to be available for whatever service—fighting or civilian—most needed them , (2) that in the fixed and mobile A R P posts all doctors under 40 should be replaced by those over that age and by part-time general practitioners , (3) that all public-health appointments during the war should be held by men over 50, and that these appointments should be freed for the time being from the provisions of the local government and sanitary orders MEDICAL PLANNING

SIR,—I have read with interest the letter from Mr Handfield-Jones in your issue of Feb 8 As he says, the Army Medical Service is reluctant to reveal the voracity of its appetite for medical officers, but this extravagance is undoubtedly the basis for the present shortage. Rumours now reach us that there is to be another call-up of medical men in the near future At this time of year, in particular, further conscription will lead to very grave difficulties, more especially in areas where the civilian population has been increased and the medical population diminished Unfortunately the British Medical Association, which one might have expected to emphasise the hardship to the community and to the elder doctors left behind, appears no longer to be the champion of its members, but rather the handmaiden of the Ministry of Health, and there is little help to be expected from that quarter

A further point which should be noted is the serious patriotism is a very real thing, but there are men, usually quite young, in whom it does not burn so brightly Why is this ? The same process is at work here as in the increase in juvenile crime, which a peripatetic correspondent of Feb 1 put down largely to irresponsibility Just as children and young persons commit antisocial acts from thoughtless selfishness, so the young men, having had so much done for them, have never even begun to think in terms of other people In taking anything that strikes their fancy children do not consider the point of view of the owner Indeed, when the question is asked in the juvenile court, "How would you like it if somebody else had taken *your* things ?" the answer "I shouldn't" has been given as apparently something quite fresh Perhaps our system of education is to blame, by concentrating overmuch on purely material things In our elementary schools everything that will add to the material comfort of the children is being supplied in abundance—the class-rooms are well lighted, well spaced and airy, the furnishing is almost more than could be desired The lavatory accommodation is adequate, so are the playgrounds But is there something lacking ? The average healthy child used to prefer toys of his own devising to anything that could be bought Half a dozen old soap boxes, an imperfect box of battered bricks, were of more permanent value to him than any mechanical toy simply because they enabled him to employ his imagination The bricks would be anything from a medieval castle to a locomotive engine within half an hour, and next day they would be something quite different Are our modern methods killing that sense of imagination ? Are we taking from the children something we can never replace, and, if so, are not we responsible for much which we deplore ?

[1] Roblin R O Jun Williams J H Winnek P S and English, J P *J Amer chem Soc* 1940, 62 2002

[2] Feinstone W H Williams R D Wolff R T, Huntington E and Crossley M L *Bull Johns Hopk Hosp* 1940, 67, 427 Annotated in the *Lancet*, Feb 15, p 217

Our opponents in this war have made it abundantly clear that they are out for world domination, for the trampling down of any who get in their way They really have much the same viewpoint as the irresponsible child—the entirely selfish one—and this outlook is fostered in Germany by neglect of everything that stands for self-reliance There everyone follows his leader, he is forbidden to think for himself, he is not even allowed freedom of thought The result is woefully apparent—a war machine which has proved its deadly efficiency But it is merely a machine, it lacks individuality and sooner or later it must break Men and women may be personally irresponsible for a time, but not for always

We may see something of the shrinking from responsibility in the practice of our own profession, particularly if we live in or near a town with a hospital A generation or so ago most of us had to depend pretty much on ourselves There were few outside aids A well-equipped laboratory was a rarity, X-ray machines were not common, and certainly were not within easy reach For diagnosis we relied on ourselves, and the evidence we were able to collect by the use of our developed senses Who does that now ? If we are in any doubt, and often when we are not, we send our patient off to this or that expert at the hospital for an opinion The opinion may be valuable, but the effect on us and on our patients may be less so For only too often we have not so much shared our responsibility as passed it on The average young doctor is well up in modern methods of diagnosis and treatment but is shy in applying them himself How many town G P s ever treat a fracture right through ? How many so much as see a case of V D ? Thirty years ago, and less, every G P felt himself competent to tackle pretty nearly everything, and *was*! Today he does not think so, and consequently plays for safety That, not infrequently, is a highly dangerous thing to do

* * *

We don't consider ourselves hardworked these days, far from it, but the usual early morning muster at sick bay keeps us pretty busy while it lasts The accepted Service idea of treatment involves seeing as many patients as possible in unit time, and delays are frowned on despite the fact that both we and our staff are largely unoccupied during the remainder of the day Thus when one day, in the middle of my list, my chief sick-berth attendant announced that the next patient was a Pole I was none too pleased, my linguistic accomplishments being limited, and I foresaw a long and tedious discussion However, in he came, a tall and well-built fellow with a charming and apparently permanent smile, his uniform smart and clean and his whole appearance most impressive He halted before my desk, clicking his heels with a sound like a whip, gave a slight bow from the waist and then relapsed into a silent immobility, obviously intending me to take the initiative I was rather taken aback when my opening sally "What is your complaint ?" spoken very slowly and deliberately, brought forth a volley of mangled Anglo-Polish which was quite unintelligible Evidently flattered by the assumption that he spoke English, he was making the most of the opportunity This flow was stanched with difficulty, and after a short and awkward pause my "chief" whispered "They usually understand French, Sir!" *I choked back the retort that* unfortunately I didn't, and delved into my hazy memories of lessons at which I learned a maximum of French grammar and a minimum of idiom Tentatively I tried "Qu'est ce que vous avez ?" to be rewarded by an intensification of the smile and another excited torrent of speech in what was presumably a second national language to him This also left me cold, so once again an impasse was reached Just as I was about to eat humble pie and demand an interpreter he suddenly said, in good and precise English, "I have " and then stopped As this was the first lucid expression I had received I leaned forward eagerly "Yes ?" I said, hoping to hear his symptoms, at last "I have " (there was a slight pause while he fumbled in his pocket and brought out a small red book) "a dictionary!" and he looked enormously pleased at having remembered the word and its pronunciation The book was rapidly thumbed and a large forefinger pointed to an astonishingly unpronounceable word against which was the English equivalent "itch" While I digested this information he rapidly stripped and displayed a sweat rash of the groins, and uttered what I took to be the word he had just showed me Not to be outdone, I commandeered the dictionary, found the English-Polish section and rapidly ran through the pages until I found the Polish equivalent of "sweat" which was some curious word like "pog" "Pog," I said, and again there was a pause, while I considered in which language to put my transitive verb At last, in desperation, I said firmly, "Pog makes " (a sort of strangled cry followed as I attempted the Polish word for itch) I looked up expecting incredulity, even indignation, but it had worked! He was delighted at this simple explanation—having evidently expected a diagnosis of tinea or pediculosis, both of which being pretty common at the time—and departed with yet another shattering heel-click But not before I, in my new burst of confidence, had sunk so low as to say "Fini"! After this brilliant success I bravely faced the next man—a French rating—with "faites voir," to his profound amazement, for his English had been more than adequate on previous occasions

* * *

If an analysis was made of papers read before the provincial medical societies I fancy it would transpire that most of them are contributed by the staffs of hospitals and specialists The general practitioners may complain that these, while serving as a modest advertisement to the contributors, do not help them much, and the society's secretary that he cannot get papers from them How are we to tap the vast clinical and therapeutic experience of general practitioners ? They see after-results from their own practices and—an important point—cases returned "cured" from all kinds of hospitals Here they seem to be in an unique position Yet our two leading weeklies and two German ones which I read contain but little of their writings I should like to see occasional numbers of these given over chiefly to contributions from the "backbone," or perhaps an occasional supplement Or general practitioners might arrange to support representatives of their number, with the requisite attributes, relieve them from practice, and set them to edit a monthly journal controlled and maintained by the practitioners, solely for contributions from their experience

---

Since the publication of the last list of subscriptions to the Medical War Relief Fund £800 has been received, bringing the total to over £17,000 practitioners" It would almost seem that there remain only the questions of when and in what form a whole-time general practitioner service should be introduced

Sevenoaks GORDON WARD

SIR,—I profoundly disagree with propositions 2 and 3 of Dr Everard Williams's letter on the future of medicine He advocates the setting up of official contraceptive clinics, but contraception is an important factor in the falling birth-rate of the country and provides a means of avoiding family responsibility Yet in proposition 4 Dr Williams advocates family allowances Proposition 3 represents an attack on individual rights The principle carried to its logical conclusion would condemn to death all those who are of no use to the state, and it is precisely against such principles of state worship that we are fighting now Either there are rights attaching to the human personality, or the personality is to be at the mercy of an omnipotent state One such right is surely that no innocent life shall be forfeit, and this plies equally to the unborn child and the mentally fective The study of the hereditary factor in mental fect or disease is still in its early stages, our present owledge does not justify us in interfering with human ghts This does not mean that I approve of the state ending *30s* a week to maintain an imbecile child d only *5s* a week to support a healthy one, we must ep a sense of proportion But in any case the comarison is not a fair one, many mentally defective atients do useful work when gathered into a community d thus in part support themselves

On what grounds does Dr Williams induce abortion a case of rape? Is it on account of the danger to the ealth of the mother especially if she is young, or is it ecause it is feared that the child will be born with hysical or mental defects? A recent publication by r Letitia Fairfield reviews about 74 cases of juvenile arturition, some of which were presumably the result f rape It showed that there was no maternal mortality, ut the forceps rate and puerperal morbidity rate were lightly increased over the normal rate Half the infants veighed less than 7 lb at birth, 18 were premature, 5 vere stillborn, and there was a high incidence of congenital defects 2 cleft palates, 1 anencephalic fœtus, inguinal hernia and 1 slight talipes These figures urely, on medical grounds alone, do not justify therapeutic abortion

The changes advocated by Dr Williams are in conflict with the moral law, and where there is conflict between that law and medical therapeutics we can be reasonably certain that bad medicine is being advocated

Southern Hospital Dartford A D WILLIS

TREATMENT OF WAR NEUROSIS

SIR,—There are points in Dr Dillon's letter of Feb 1 which I should like to try and answer

Dr Dillon asks by what criteria an assessment of the personality can be made before disposal In the vast majority of cases the main criteria are the reactions of the individual to danger—not only his reactions to current dangers, such as any form of enemy action, but his reactions to danger real or imagined throughout life What is the history we obtain so frequently from men who, in my opinion and that of others, must be discharged? Throughout life they never lived dangerously, have avoided any threat to their security A nervous childhood, mother-fixed, regarding the outside world as full not of wonderful things to be enjoyed but of dangerous things to be avoided They have never climbed a tree, never played football, never fought a fight For them throughout life fear has always meant flight, they have lived their days not endeavouring to tolerate anxiety but avoiding it Quite possibly there may have been no overt neurosis before joining the Army because they have so planned their life as to avoid the conditions which would produce anxiety I do not believe that this type is amenable to psychotherapy because there is no real desire for it, they have found a ring fence within which they can be reasonably content and they only desire to get back within it again They may even as civilians avoid a breakdown under enemy action because they can either flee or remain immobile in a shelter, but when in the Services they cannot obey their instinctive reactions to danger they break down They may have had reasonably well-paid but sheltered occupations, or they may have been content on the dole or receiving public assistance, or content to drift from casual ward to casual ward. In all there is the same basic mechanism of flight from any threat to their security Most of us will agree that these are not the cases which fill our psychiatric clinics in peace-time They have made their adjustments, and only war with its threat to personal safety breaks down the barriers they have built

This war is different from the last, particularly because recruits are exposed to the threat of enemy action probably as soon as they join the Services, and may even have been exposed to it before There are not the chances as in the last war of getting training, discipline and some possible building up of aggression or ideals of service before being exposed to the threat or reality of danger Many of the cases we are now seeing have only been a few weeks or months in the Army, from the beginning they have reported sick whenever possible, may have never fired a rifle, and no instructor would trust them with one I do not believe that there is any great number of these cases in proportion to the number of the present intake into the Army, and I am sure they must exist in any conscripted army of any nationality They must, however, come into the net of the neurosis centres, and those of us who work in them may be depressed at times by their numbers

I should be the last person to belittle the use of psychotherapy, but there must be something to build on, some real desire not only to be symptom-free but to meet and stand up to war service conditions Discharge rates are not very satisfactory, but will be more so when the present system of following up has brought replies from units A neurosis centre has a net with a small mesh and brings in not only anxiety states and hysteria but also epileptics, mental defectives, psychopathic personalities and others I quite agree with Dr Dillon that many neurotics have made good soldiers, but they are different in the type of neurotic mechanism from those I have referred to I think I can assure Dr Dillon that psychotherapy is still being used in suitable cases

MAURICE B WRIGHT,
Whitchurch Psychiatrist, E M S

A BLASTED HORSE—AND OTHERS

SIR,—The article on what a layman may call a shell-shocked pheasant in your issue of Feb 8 suggests that similar particulars may be of interest in the case of a horse

Idol, a very good dray-horse, six years old, had been working for eight months for a London brewery Last autumn, at 4 A M, a heavy H E bomb demolished a building and twenty houses about eighty yards from the stable, which is on the ground floor Intervening houses prevented any damage being done to the building, except a skylight, but of course there was a terrific bang and concussion Fourteen horses, then probably all asleep, were all right except for being frightened and restless Idol and another lay unconscious The other (aged eleven) recovered in two hours, and with massage treatment was at work forty-eight hours after, and has suffered no permanent ill effect Idol lay as dead for over four hours, with such a slow pulse that the stable foreman decided it was hopeless and the humane killer was brought to kill him Suddenly he shivered all over and got up, but could not use his hind quarters to walk Fomentations and massage were applied and a week after he was able to do light work, constantly needing rest days but working four days out of six There was slight lameness in the hind quarters

Three months afterwards there was a direct hit on the same stable, killing two horses outright The remaining twelve were able to walk out and most were at work that day Idol had a bad relapse, and now a month later is little better He cannot back and finds difficulty in turning, the symptoms being paralysis along the spine It is feared there will be little more work for him in London, though it is intended to give him six months' rest at grass during the summer, in the hope of a cure

Other animals in a country district were affected after land-mines had been dropped The rabbits—even in their holes—suffered from shock and hopped out of them aimlessly and could be picked up by hand The cows similarly behaved in a dreamy way, refused to eat and had to be slaughtered

Ware, Herts H F BUXTON

position arising from the fact that many medical men in the Services are getting out of touch with medicine, and deprived of clinical work will get increasingly rusty as the war goes on As one ex-house-surgeon writes to me "One is a mixture of clerk, soldier and first-aid man, in that order" The remedy would appear to lie with the Army Council, who should no longer insist on a medical officer to so many men, for units stationed in this country, but should allow local doctors in many areas to do the half-hour morning sick parade, all more serious cases being sent to hospital as at present

Lincoln G A **Bagot Walters**.

PAUL-BUNNELL TEST IN GLANDULAR FEVER

Sir,—I agree with Professor Himsworth when he says in his letter of Feb 8 that careful record-keeping is necessary so that we can find out if the Paul-Bunnell reaction is specific for glandular fever and if we must classify separately similar syndromes with a negative reaction But I don't think he will obtain the distinction he wants if he uses monocytosis as a criterion The blood picture of glandular fever is highly characteristic and four groups of cells among the increased mononuclears can be distinguished

1 Typical lymphocytes
2 Typical monocytes
3 Plasma cells and large cells with dark basophilic cytoplasm probably related to plasma cells, these include the "Turk" cells
4 Cells which resemble monocytes but do not have lobed or indented nuclei, these cells have been classified by various authors as lymphocytes, monocytes, glandular-fever cells, or simply as abnormal mononuclears, they are very characteristic

The proportion of these groups varies in every case, but group 4 is always prominent It is this composite picture that is so typical of glandular fever, and not the presence of any particular monocytosis or lymphocytosis Neither Dr Barber nor Dr Fuller gives clearly typical differential white-cell counts, probably the class of lymphocytes includes atypical forms Monocytosis is known to accompany infections of the mouth and throat unaccompanied by general symptoms like those of glandular fever (e g Hartfall 1934), and a point that suggests that Dr Fuller's patients had not got glandular fever is that the sternal marrow in one case was unaffected In the few patients I have examined the marrow always contained cells of groups 3 and 4 and increased percentages of lymphocytes and monocytes This may be helpful in differentiation

With regard to technique, a staining combination including Giemsa gives the best results, supravital staining unfortunately gives no more help than this in classifying the abnormal mononuclears.

In the meantime it is probably best to follow Dr Fuller's example and not report cases as glandular fever if the Paul-Bunnell reaction is negative

Research Department, Manchester Royal Infirmary

ENDEMIC FLUOROSIS

Sir,—In your leader of Feb 15, it is stated, in reference to mottled teeth, "The discoloration appears as opaque white or brownish patches on the enamel and is likely to occur in those who drink water containing more than 4 5 parts per million of fluorine" Since this might give the impression that water of less fluorine content is unlikely to cause mottled teeth it should be noted that there is considerable evidence (mostly American) that drinking water is safe in this respect only if it contains less than 1 part per million of fluorine I have estimated the fluorine content of numerous water-supplies in Great Britain, and I consider that the limiting figure for drinking water-supplies of 1 part per million of fluorine should provisionally be accepted

Victoria Street, E C 4 E V **Suckling**

THINGS TO COME

Sir,—May I offer for the consideration of those who would plan our future some reflections upon 1364 expressions of opinion which lie on my desk? They are some of the replies received by the Medical Practitioners Union to its scheme for a national salaried service for general practitioners This scheme was circulated to every doctor in the country and their opinions were invited by the provision of a blank sheet with the caption "I am / am not in favour of the principles underlying this memorandum and offer the following criticisms" The replies with which I am dealing were analysed several weeks ago but others which have come in since seem to be very similar in character We may therefore take it that the 1364 opinions, less 71 which were indefinite, are likely to afford valuable and reasonably accurate evidence of what medical men are thinking today There were 849 replies in favour of a whole-time service and 444 against This is an impressive majority but it nevertheless conveys an inaccurate impression By the mysterious operation of human fallibility the memorandum failed to suggest any compensation for the capital sunk in practices and this was very alarming to those who had purchased, or were still purchasing, shares in established practices Many of these recorded a vote against the scheme on no other grounds, although it was quite clear from their other comments that they were not at all opposed to the principle involved The confusion between principle and detail was seen also in other replies, and I think it would be an understatement to say that no less than 75–80% of those who expressed an opinion were willing to accept the principle of whole-time salaried service

What has caused this great departure from the traditional attitude of the profession? I think there can be no doubt that the National Health Insurance Acts are in great part responsible, although economic facts have been of decisive importance Insured persons have not shown themselves particularly grateful for the services rendered by doctors, and have been increasingly ready to call them out at any time of day or night with little regard to the real needs of the case Doctors are also forced to make many millions of visits a year for no better purpose than the giving of certificates on some one particular day convenient to the agents of approved societie These are two examples of a type of demand which has upset the old balance between doctor and patient The latter now expects as his right (backed by disciplinary measures) the sort of service which he formerly accepted with gratitude and repaid with some degree of consideration for his doctor It is possible that I have put this too strongly, but I think it is largely the burden of such service that causes so many doctors favourable to the scheme to harp on the need for settled hours, days off, and regular holidays without the expense of providing a locum It is scarcely necessary to say much of the economic factors which bear so hardly on general practitioners Every doctor knows that the low insurance fee and the ever-increasing encroachment of state services have been powerful factors in turning men's minds towards the advantages of a regular salary with a pension to follow It is in the light of such considerations as these that we must weigh the hundred or so replies which insist that the individualistic type of practice has the great advantage of involving competition, and allows a practical idealism which, they say, is unlikely to flourish under a state system These replies come mostly from the older members of the profession They do them honour, for they are prompted by memories of lives spent in exacting and unselfish work of a sort for which no praise can be too high It will be generally agreed that we must strive to carry over these ideals into a state service, but to the more modern mind ideals alone are not enough and we have to realise that the full advantages of medical knowledge can no longer be brought to bear by isolationists A new generation has come into being, neither better nor worse than the old, but forced by circumstances to think and to work along different lines In the medical world it is the line of coordinated state service which has now the most followers, and those who plan for the future must take account of this fact, in its ethical as well as its practical aspects

There is undoubtedly a widespread revolt against general practice as we know it today How extensive this has become may be judged not only from the general tenour of replies received but also from the following opinion expressed by a teacher not unknown to fame "As a general outline of the new service your summary is excellent, and my teaching experience of 35 years amongst medical students convinces me that it will be whole-heartedly

Diphtheria Immunisation in Scotland

Mr ALFRED EDWARDS asked the Secretary of State for cotland how many cases of diphtheria in immunised, and on immunised children, respectively, were recorded in the unty of Aberdeen in the years 1938, 1939, and 1940, and hether any of these were fatal —Mr T JOHNSTON The quired figures are —

	1938	1939	1940
iphtheria in non immunised children —			
Cases	186	149	114
Deaths	11	7	3
iphtheria in immunised children —			
Cases	42	16	7
Deaths	*0*	*0*	*0*

Mental Hospital Staff

Mr V MCENTEE asked the Minister of Health in what rcumstances attendants at the Rampton Mental Institution ere required to work approximately 113 hours a fortnight, ncluding meal times, as against the 88 hours per fortnight quired of the staff at Broadmoor Criminal Lunatic Asylum —r BROWN replied I am making inquiries

WILLIAM BULLOCH

M D , LL D ABERD , F R S

To many the death of Professor Bulloch, the historian f bacteriology, is the closing of an epoch, for he was a link ith the great pioneers of that science and his remarkable emory and sense of the dramatic and ludicrous enabled im to discuss its historical figures as though he were ne of them History was his abiding passion, but not so much the history of trends or events as of individuals He was acknowledged master of the bacteriological "conte drolatique," but as his scholarly and critical "History of Bacteriology" showed, he could also tell a sober story well

Russell London

William Bulloch was born in Aberdeen in 1868 and died in the London Hospital on Feb 11 after an operation. He was educated at the grammar school there and at the university, and after graduating in medicine with highest honours in 1890 he visited several continental centres of learning studied under Robert Koch, and finally returned to London to work at King's College Later he was appointed assistant professor of pathology at University College and bacteriologist to the Lister Institute In 1897 he was offered a chair of bacteriology and went to complete a brilliant triumvirate at the London Hospital, where Leonard Hill was already ecturing on physiology and Arthur Keith on anatomy For the rest of his working life Bulloch remained faithful to the London, although his wide knowledge and his transparent honesty caused him to be invited elsewhere to fill important positions of trust Thus he was chairman of the governing body of the Lister Institute, he was an original member of the Medical Research Council, and hairman of the committee which prepared its System of Bacteriology in 1930–31, he was a member of the Government's foot-and-mouth disease committee, he examined for the universities of Aberdeen, Leeds and Liverpool Yet at the many committees he attended he seldom took an active part in a discussion—it gave him pleasure to sit and study his colleagues Though without personal ambition he received many honours, he became a fellow of the Royal Society in 1913, he received an honorary degree from his alma mater in 1920, he was Dobell lecturer to the Royal College of Physicians in 010, Tyndall lecturer to the Royal Institution in 1922, and Heath Clerk lecturer in 1936 On these last lectures his history of bacteriology, published in 1938, was based

Yet with all this Bulloch remained to his students the most accessible of men and the picture we reproduce here will remind them of this middle period of his career One of these students has recalled how on his door there hung perpetually a notice "This is my busy day," but, he goes on to say, "this neither kept Bulloch in or others out, for he was the most communicative of men, ready to exchange ideas or tell a story Afternoon tea in the laboratory was a feast of badinage, reminiscence and kindly mimicry, and his dinner parties at home were gastronomic and intellectual banquets not to be forgotten The art of medicine exasperated him—it was too hit-or-miss for his scientific taste—and he professed a supreme contempt for clinicians and clinical medicine, but when anyone near to him showed the least sign of ill health he would urgently summon the best available clinical opinion" Summing up as a contemporary and countryman, Bulloch's personal qualities, R H writes "A shrewd judge of human nature and intensely interested in the foibles and vagaries of his fellow men (indeed, something of a gossip) and gifted with a dry Aberdonian humour and a caustic wit, Bulloch had an immense fund of amusing, if not always strictly accurate, stories which he poured out with an admirable power of mimicry His shafts, however, were always directed against pretentiousness and humbug in any form; real merit he never failed to recognise and encourage Ill health clouded his last years and dimmed his spirit, but those who knew him at his best will always remember him as a man of the highest scientific ideals and a warm-hearted, witty and entertaining friend"

Another personal tribute is from one who collaborated with Bulloch in his important work on hæmophilia:

"Those who were Bulloch's pupils or assistants can put it on record that though he did not figure to a notable extent in any great advance in knowledge, though he was not in the ordinary sense a notable teacher, nor administrator, nor man of affairs, he nevertheless exerted a great influence on the development of bacteriology in this country Indeed most of his pupils derived sufficient from him to rise to positions of which he was proud Bulloch was not only honoured in his own country. He was the respected and intimate friend of many of great repute abroad When I visited Ehrlich during the '606' boom, after handing in my card with Bulloch's, I was shown into a waiting-room full of dejected visitors I had hardly sat down before the door was flung open and a little man burst in and cried, 'Who comes from Bulloch?' He spent an hour with me before attending to his other visitors

"It is difficult to analyse the route by which Bulloch's influence spread He had himself no passion for research and sometimes gave the impression that he did not appreciate it; but those who knew him well came to learn that his lack of enthusiasm was due to his native caution He had a knowledge of the literature so profound that he required very strong evidence before he accepted a current piece of work as novel If sometimes in his earlier days his criticisms were devastating, they at least reduced the number of one's errors and promoted one's successes He was a good director in that he was a good and trusted umpire Even when we had left him and were getting a bit senior ourselves, we were often surprised at his knowledge of what we were doing That we remained in his mind was often brought home to us when he told stories of our early eccentricities and improved them in the passing years In his earlier period when he was defending with heat a new subject which sometimes challenged vested interests, he was apt to take dislikes to people, especially those in authority whose duty it is sometimes to take ruthless decisions But during the last twenty years of his life, with a happy marriage, he developed a serenity of outlook which gave great pleasure to his friends because they thought he deserved it"

P F

DR WILLIAM TAYLOR DOYLE ALLEN, a well-known Liverpool general practitioner, died at Heswall, where he had gone to live after his retirement from practice consequent upon a serious illness He qualified in 1895 as M B R U I, and became resident medical officer of the Parish Infirmary at Liverpool He later held the post of assistant surgeon to the now defunct St George's Hospital for Diseases of the Skin, and was physician to the Liverpool School for the Blind For many years, until he retired, he practised in Mount Pleasant He was a sound family doctor, genial and friendly and with a quiet humour which made him good company He leaves a widow and one son, who is studying medicine

Parliament

No issue of domestic politics has excited more bitter controversy in recent years than the means test applied to applicants for unemployment assistance or supplementary pensions It was natural that in the new atmosphere of the political truce, inaugurated last year by the accession to office of a National Government including most of the leaders of the former Labour Opposition, an early effort should be made to remove this serious stumbling-block to real national unity The result was a compromise, which while still retaining a means test represents an honest and sincere attempt to get rid of the principal objections raised to its application On Nov 6 of last year Mr Churchill gave a pledge to the House of Commons which has since been embodied in legislative form under the title of the Determination of Needs Bill This measure came before the House of Commons last week for second reading How well its draughtsmen had interpreted the Prime Minister's pledge was shown by the welcome which the bill received from all parties It was generally agreed that the Chancellor of the Exchequer was quite justified in describing the bill as "a far-reaching reform," and in recommending it as "an important mark of our confidence in the final issue of the present struggle and of our determination not to be deterred from continuing to the limit of our ability to improve the conditions of the people" Sir Kingsley Wood explained that the first part of the bill was designed to abolish the household means test and to make the test one of personal need based on certain principles which had been indicated The other part of the bill, he said, gave effect to the undertaking given by his predecessor, Lord Simon, in relation to war savings and contained certain modifications of the previous proposals to meet objections which had been advanced Sir Kingsley Wood made it clear that the intention was to confer the benefit exclusively on the war saver, since the incentive would be gone if the provision applied to savings made at any time But in order to meet genuine misunderstandings about the pledge the Government had decided that, while the distinction between war savings and other savings should be retained, the date at which it would be possible to transfer pre-war savings into war savings would be advanced to Aug 14, 1940 The overwhelming majority of members, including the Labour Party, gave the bill their blessing Mr Pethick-Lawrence, a doughty critic of the means test in the past, voiced the opinion of the bulk of the Labour members that the bill went a long way to meet their wishes "It is an immense change," he said, "and constitutes immense progress" It shifted the obligation to look after those who were old or out of work from the family and the household to the community as a whole Mr Pethick-Lawrence vigorously denounced the action of certain members of his party who had put on the order paper an amendment which he said would have the effect of wrecking the measure He twitted the sponsors of the amendment with wanting to pose as champions of the oppressed, while in fact they were playing politics and doing their best to sabotage an agreed compromise solution of a complicated controversial question He called on those who had the welfare of the unemployed and the old-age pensioners at heart to disown the amendment and support the second reading Mr Graham White, speaking for the Liberal Party, also agreed that the bill would bring great benefits to a number of people while it would injure none At the same time he warned the House that a resurvey and recasting of our social services would be one of the most urgent tasks of the post-war period The main argument of the malcontent Labour minority who supported the amendment was that the bill failed to give full effect to the Prime Minister's pledge Mr Ernest Bevin, the Minister of Labour, wound up the debate for the Government with a vigorous speech in which he stoutly denied that there had been any breach of faith This point of view was amply confirmed in the division lobby where the critics could only muster 19 votes against 173 in favour of the bill

Universities and War Damage

The position of the universities and other institutions which suffer war damage was raised at the committee stage of the War Damage Bill in the House of Commons on Feb 11 Mr K W M **Pickthorn** moved an amendment exempting "bodies of persons (whether incorporated or not) who occupy premises for, or in connexion with, the advancement of religion, education, science or research," from compulsory insurance under the business scheme of the goods on their premises but leaving them free to do so if they wish He said that the bill attempted to distinguish between assets held for business purposes and assets held for domestic purposes, or for the purposes of living rather than of earning a living The peculiar difficulty of the universities and colleges was that they were both a kind of home and a kind of business No-one suggested that chattels which might be described as luxuries or amenities should be restored until the country had fully recovered from the war, but, so far as natural resources permitted, it was desirable that chattels without which the nation could not continue should be replaced —Sir W **Jowitt**, solicitor-general, said he could not accept the amendment on principle It seemed to ask that a university should be regarded as carrying on business, and the Government thought it undesirable to exempt from compulsion persons carrying on business and to allow them to pick and choose what goods they would insure He agreed that the objection did not apply so strongly to universities as to ordinary businesses, and the Government would use their powers under clause 45 to exempt certain classes of the non-essential equipment at universities which would have to be very carefully defined The Government would no doubt seek the help of the universities themselves —Mr **Edmund Harvey** said that the assurance given by the solicitor-general would give real satisfaction to the universities, but he regretted must be regarded as business concerns It was true the universities received help, but every student more than the value of his fees The universities carrying on at a great loss and were only able to do through benefactions and grants The amendment by leave withdrawn

QUESTION TIME

Financing of Rest Centres

Dr H B **Morgan** asked the Minister of Health, with ence to the departmental circular No 2154, what was policy of his department with regard to the rest centres ready for use by homeless persons in cases emergency through enemy action, and whether authorities would be reimbursed expenditure for services as heating, caretaking, and maintenance staff, if, in their discretion, staff for this purpose was considered necessary in rest centres —Mr H **Holdsworth**, Lord of the Treasury, replied A circular was issued to county councils and county borough councils on Feb 6, informing them of the Government's decision to reimburse public assistance authorities the whole of their approved expenditure, from the inception of the scheme, on providing at rest centres for the immediate needs of people who are made homeless or leave their homes as a result of enemy action A large measure of discretion has been allowed to local authorities in providing for this service and approved expenditure for heating, caretaking and maintenance staff, would be included in the reimbursement

National Health Insurance Benefits

Mr F **Collindridge** asked the Minister when it was proposed to give to the House a report of the examination referred to in his speech, on Oct 17, 1940, that Government departments had been making into health insurance and associated questions —Mr **Ellis Smith** asked if he was aware of the extreme urgency of the need to increase the benefits payable under the National Health Insurance, in particular, sickness, maternity and disablement benefits by what amounts it was intended to increase the benefits and if he could make a statement on the matter in view of the urgency —Mr G H **Oliver** asked whether he was aware of the hardship suffered by persons in receipt of disablement benefit paid under the provisions of the National Health Insurance Acts by reason of the increase in the cost of living and whether he would consider increasing the benefit, as has been the case in many other benefits and allowances as a result of war time conditions —Mr **Brown** replied While I am not as yet in a position to make a statement on this subject, I hope to do so soon

GEOFFREY RAYMOND EDWARD MAXTED

M.B BRIST ; SURGEON LIEUTENANT R.N.V.R.

rgeon Lieutenant Geoffrey Maxted, who has been ted killed as the result of enemy action, was the ger son of Mr. E B Maxted D.Sc., a lecturer he department of chemistry in the university of Bristol. Geoffrey Maxted was educated at King's School Canterbury, and at the University of Bristol, where he graduated in medicine in 1938 Prof C Bruce Perry writes:

Geoffrey Maxted obviously enjoyed all his work and exhibited a healthy scepticism to traditional views As a student, stimulated by claims that some infections are more common among persons of certain blood-groups he investigated the distribution of the main blood-groups in matic heart disease. Although the results were nega- it was a useful study carried out with care and for work he was awarded the Martyn memorial scholar-

The paper embodying the results was published in *Archives of Diseases in Childhood* (1940 15 181)

fter graduation he held house-appointments at the tol General Hospital, at Southmead Hospital and at Leicester Royal Infirmary

t the outbreak of war he volunteered for the V.R and received his commission in December 9 He was killed just after his 26th birthday He ed the sea, swam and dived well, and had sailed his small boat under many conditions which proved his rage, including a voyage in bad weather from the th Coast round Land's End to the Bristol Channel had a happy disposition and an attractive personality, his death will be felt as a personal loss by all who e into contact with him

ROBERT DUDLEY ROPER

M.B. CAMB ; SURGEON LIEUTENANT R.N.V.R.

Dr R. D Roper, who died on Feb 2 aged 34, was the of the late Dr. H. J. Roper of Leeds He was cated at St Edwards School, Oxford, and St. John's lege Cambridge and qualified M.R C.S. from Bart's 1933 He took his B Chir. the same year and obtained M.B in 1935 After qualification Roper became a ualty house-surgeon at Bart's, but he went to Charing oss as house-surgeon to the ear, nose and throat de- tment and here he took up anaesthetics as a specialty. er becoming honorary anaesthetist to the hospital e was also anaesthetist to the Hospital of SS John and zabeth and to the Connaught Hospital at Waltham- ow and he had built up a growing private practice in esthetics. When war broke out he joined the E.M.S t he found the work uncongenial and as soon as he uld obtain his release he volunteered for service with e R N V R, for he had always loved the sea. A friend ls how as a student he spent many of his happiest hours Burnham-on-Crouch sailing a yacht in which he had a re. Travel and the theatre were his other hobbies. d he had a large collection of books among which he ighted to spend quiet afternoons.

Dr. ELIZABETH HURDON

Miss M. M. Chadburn, chairman of the cancer com- ttee and surgeon to the Marie Curie Hospital, writes: lizabeth Hurdon made no claims and her distinction was e acknowledged excellence of her work. She combined e scientific and the clinical to an unusual degree she had orked and collaborated with the distinguished staff of the ohns Hopkins Hospital and come in contact with many f the greatest medical minds of her day in America he had done important work both in hospital and in rivate practice in Baltimore she had travelled widely nd knew the clinics in France Germany, Sweden elgium and America And when the Marie Curie Hospital was started the committee felt that they were rtunate in obtaining her services as radium officer and rector of the work; she understood and was able ccessfully to contend with the difficulties attached to he rather unwilling acceptance of women's work in ome quarters of the profession and she won the admira- on and respect of her colleagues both male and female wherever her work was known The Marie Curie Hospital owes much to her judgment, scientific mind and independence of thought

Dr Hurdon was not only a scientific worker She was an arresting personality a stimulating and interesting companion a good talker, interested in what was going on everywhere in the world and also in the small things of everyday experience and in the fortunes and misfortunes of her friends When she died she had just finished a treatise on the radiological treatment of cancer which I hope may be published shortly In one of her last letters to me knowing all about her own illness and imminent death she said she hoped to finish it "in time" And I believe she did

MEDICINE AND THE LAW

Damages for Mental Shock

ONE more case has been added to the series of awards of damages for nervous shock without visible injury At the Norfolk assizes Mrs Englestown was given £450 general damages and £250 special damages in her action against a defendant who had negligently caused an accident which she witnessed. The Rev. Mr. Shead drove his car out of a side road and collided with a lorry driven by Mr. Hardy, a haulage contractor Mrs. Englestown, walking on the footpath was not touched by either vehicle; but she complained that her involuntary witnessing of the occurrence had induced a state of collapse There was medical evidence that she was suffering from hysteria, she was afraid of cars. one doctor said that, when he attended her recently, she shrieked at the mention of a motor-car; her condition, he said, was now worse than it was two years ago It was stated that she refused to go into an institution, and yet there was little prospect of her recovery unless there was institutional treatment. She had sued both Mr. Shead and Mr Hardy. The judge found that the former was to blame for the accident: he ordered him to pay the whole of the damages and also Mr Hardy's costs

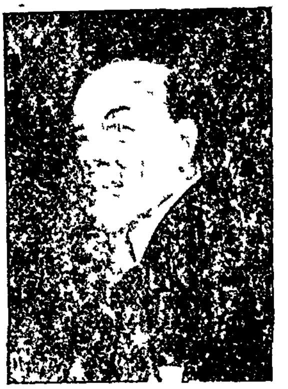
The modern decisions include Hambrook v Stokes (1925) where a mother was held entitled to damages if she could prove that she suffered shock from a reasonable fear of immediate personal injury to herself or her child. If she knew that a runaway vehicle was descending a hill on which her child was standing and if she could prove that she suffered mental shock as the reasonable consequence of the negligence of the defendant who left the vehicle in a dangerous position unattended then she would recover damages Lord Atkin then Lord Justice Atkin, was prepared with characteristic courage to extend the liability. The negligent person who had failed to look after the vehicle would be liable not merely if shock resulted by reason of a mother's natural anxiety for her child but even where a bystander felt apprehension for the safety of some third party. How much further one wonders, can the possibilities of emotional disturbance be exploited? A writer in the *Canadian Bar Review* in 1939 cited two instances. In Bielitski v Obadiak (1922) the Saskatchewan court of appeal allowed a wife to recover damages for shock caused by her having seen the defendant striking her husband. This was not far removed from the facts in Hambrook v Stokes, but in the second instance the Nebraska supreme court went further. In Rosmussen v. Benson (1938) a dairyman had bought some sacks of bran for his cows from a seller who had forgotten that he treated the bran in one sack with arsenic in order to poison insects The dairyman saw five of his cows die next day and worked himself into such a state of anxiety about his cows and the possible poisoning of his customers that he fell ill and subsequently died. The Nebraska court held that the dairyman's executors could recover damages from the negligent seller of bran for the shock and its consequences

In 1939 came an English extension of principle in the case of Owens v. Liverpool Corporation where a Liverpool tram negligently collided with a hearse containing a coffin. The mother and uncle of the deceased were being driven with two other relatives at the head of a funeral procession behind the hearse They were not themselves in any danger; they were not anxious for the safety of any living person but their emotions were

HAROLD SCURFIELD

M D. EDIN , D P H

Dr Harold Scurfield who died at Letchworth on Feb 8 was for seventeen years medical officer of health for Sheffield, where his wide knowledge of public health was placed without reserve at the disposal of any cause which he championed



Elliott & Fry

Born at Sunderland in 1863 he went to school at Birkenhead and afterwards studied medicine at Edinburgh, where he played rugby for the university He graduated in 1889 and after a brief spell as medical officer at the Post Office he returned to his native Sunderland as surgeon and agent to the Admiralty Six years later in 1896 he was appointed medical officer of health for the borough and port In 1904 he moved to Sheffield, where he succeeded (Sir) John Robertson on his call to Birmingham The health officership to the municipality was in each case combined with the chair of public health at the university Scurfield was also examiner for the University of Oxford He had a deep and abiding interest in the problems of tuberculosis, infant welfare and school hygiene, and in the midst of this busy life he found time to translate Nocard's " Les tuberculoses animales " In 1912 he reported to the International Congress of Tuberculosis when it met at Rome on the control of tuberculosis in the British Isles, and in 1919 he contributed the volume on infant and young child welfare to the Story of the English Public Health which was appearing under the editorship of Sir Malcolm Morris

In appearance Scurfield was tall austere, rather heavily bearded, and a little gruff Within he was modest, inquiring and singularly responsive to the claims of family life and of social service He was an untiring worker with the faculty of codifying in his mind what he read and observed so that at the appropriate moment they crystallised in a policy or an article without obvious effort And he had that instinctive interest in little things that may sometime become important In moving about on his lawful occasions and on constant visits to congresses at home and abroad he came to know what everyone was doing and was as familiar with Nathan Straus's home pasteuriser, Octavia Lewin's snuff and May Mellanby's rickety puppies as he was with the albuminoid ammonia in drinking water or the temperature of a refuse dump This it was that made him welcome as a visitor at any scientific gathering and as an unsigned contributor to our columns over many years of his nominal retirement to Folkestone, when he was still as busy as in his official life

Dr Scurfield was twice married By his first marriage to Charlotte Bray in 1891 he had no children, by his second in 1901 to Mary Bazeley who took a prominent part in social work at Sheffield he had four sons and four daughters

ROBERT CRAIG DUN

M B EDIN , F R C S

Mr Craig Dun died at Shrewsbury on Jan 31 after an operation In his early career he was assistant surgeon to the Stanley Hospital, Liverpool, but soon after his appointment to the Children's Infirmary in 1900 he decided to devote himself entirely to the surgery of children At the infirmary his colleagues included two outstanding children's physicians, Peter Davidson and Percy Marsh Dun served the infirmary (later to become the Royal Liverpool Children's Hospital) for 32 years, until he retired on reaching the age-limit

Dun had a broad thick-set figure, with large hands which in the operating-theatre worked with exquisite neatness and gentleness He was compact of quietness, serene courtesy and a strength which was never aggressive To watch him do a cleft palate or an intussusception was a delight, he was so obviously an artist, delicate in his technique, considerate to the frail tissues on which he worked He was equipped for all types of surgery, and did beautiful work in cranial surgery among his child patients His colleagues recognised his solid qualities by calling him to the chairmanship of the Liverpool Hospital Staffs Association, a position which he held for several not too easy years in its early days

He was the son of Mr Finlay Dun of Edinburgh and was educated at Loretto He qualified M B at Edinburgh University in 1893, and took his B Sc three years later He did postgraduate study at Berlin and Berne, served in the South African War, and became a lieut -colonel in the R A M C during the last war. He was a past president of the Liverpool Medical Institution After his retirement, he went to live at [illegible] Manor, near Shrewsbury, where he enjoyed his garden and the life of the countryside

JAMES ALLAN

M D ABERD , D P H

Dr James Allan, who died at his home in Leeds on Jan 28, aged 88, was until 1925 medical superintendent of St James's Hospital He took the M B at the University of Aberdeen in 1877 and the M D three years later On graduation he served as house surgeon and house-physician in the Liverpool Northern Hospital and then, for another two years, as assistant medical superintendent of the Wandsworth and Clapham Union Infirmary He went to Leeds in 1881 as medical superintendent of the old union infirmary, later St James's Hospital, a post which he was to hold for 44 years To this work he devoted himself heart and soul no man was more conscientious or diligent in the discharge of his duties He developed and improved the nursing service at the infirmary, and instituted successful courses of lectures which paved the way for the establishment of a nurses' training-school A first-rate administrator, he was also keenly interested in clinical work and in pathology His favourite time for post-mortems was 10 P M and he expected his resident assistants to b there He was a member of the Leeds and West Riding Medico-Chirurgical Society and its president in 1907-08, and an original member of the Leeds Pathological Club

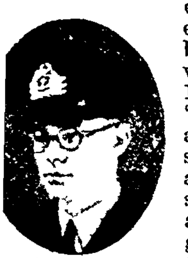
Tall, dignified and with a fine open countenance, Dr Allan was an outstanding figure in any company He was a man of few words but strong convictions, and not readily deflected from a course once decided upon Shy and reserved, he was not easy to get to know, but he had many good friends and warm admirers, and with them he could be both witty and amusing—even sarcastic if the occasion demanded He was buried with his forbears in his native village of Birnie, Elgin

SIR PENDRILL VARRIER-JONES

Prof V H and Mrs Mottram write The notices of Varrier-Jones's death have not, we think, sufficiently brought out two qualities of his which endeared him to his friends and patients The first was a power of sustained, witty, almost frivolous but always clever conversation We have sat at his dining table at Papworth Hall—a table made somewhat ‘intimidating by the brass plates let into it commemorating the august Presences who had sat at it—and listened delightedly while he made fun, and exhilarating fun, of himself, the world, the flesh and even the devil In all this he was always kindly, without malice, but as clearsighted as a hawk We never gathered what his Weltanschauung was, nor his politics, and we believe that there was only one thing about which he had no hint of doubt and that was the idea at the back of the Papworth settlement We think that all must grant him the truth of that magnificent conception The other quality we noticed as he took us round the settlement was his detailed, friendly and fatherly interest in all his patients He had the history of each at his finger tips and an insight into their psychology which certainly enabled him to turn that psychology into account in bringing about a cure of their tuberculosis If we were pressed to answer where his greatest genius lay we think we should say just this that he realised that tuberculosis should be attacked on every side and that not the least side was through the patient's psychology, and that he shared with royalty the gift of remembering through the years the personal details of the lives with whom his work brought him into contact

GEOFFREY RAYMOND EDWARD MAXTED

M B BRIST , SURGEON LIEUTENANT, R N V R



Surgeon Lieutenant Geoffrey Maxted, who has been ported killed as the result of enemy action, was the unger son of Mr E B Maxted, D Sc , a lecturer the department of chemistry in the university of Bristol Geoffrey Maxted was educated at King's School, Canterbury, and at the University of Bristol, where he graduated in medicine in 1938 Prof C Bruce Perry writes "Geoffrey Maxted obviously enjoyed all his work and exhibited a healthy scepticism to traditional views As a student, stimulated by claims that some infections are more common among persons of certain blood-groups, he investigated the distribution of the main blood-groups in eumatic heart disease Although the results were negave it was a useful study carried out with care, and for is work he was awarded the Martyn memorial scholarip The paper embodying the results was published in ie *Archives of Diseases in Childhood* (1940, **15**, 181)"

After graduation he held house-appointments at the ristol General Hospital, at Southmead Hospital and at ie Leicester Royal Infirmary

At the outbreak of war, he volunteered for the N V R and received his commission in December, 939 He was killed just after his 26th birthday He oved the sea, swam and dived well, and had sailed his wn small boat under many conditions which proved his ourage, including a voyage in bad weather from the outh Coast, round Land's End, to the Bristol Channel He had a happy disposition and an attractive personality, nd his death will be felt as a personal loss by all who ame into contact with him

ROBERT DUDLEY ROPER

M B CAMB , SURGEON LIEUTENANT, R N V R

Dr R D Roper, who died on Feb 2, aged 34, was the on of the late Dr H J Roper of Leeds He was ducated at St Edwards School, Oxford, and St John's College, Cambridge, and qualified M R C S from Bart's n 1933 He took his B Chir the same year and obtained is M B in 1935 *After qualification* Roper became a casualty house-surgeon at Bart's, but he went to Charing Cross as house-surgeon to the ear, nose and throat department, and here he took up anæsthetics as a specialty, later becoming honorary anæsthetist to the hospital He was also anæsthetist to the Hospital of SS John and Elizabeth and to the Connaught Hospital at Walthamstow, and he had built up a growing private practice in anæsthetics When war broke out he joined the E M S but he found the work uncongenial and as soon as he could obtain his release he volunteered for service with the R N V R , for he had always loved the sea A friend tells how as a student he spent many of his happiest hours at Burnham-on-Crouch, sailing a yacht in which he had a share Travel and the theatre were his other hobbies, and he had a large collection of books among which he delighted to spend quiet afternoons

Dr ELIZABETH HURDON

Miss M M Chadburn, chairman of the cancer committee and surgeon to the Marie Curie Hospital, writes Elizabeth Hurdon made no claims and her distinction was the acknowledged excellence of her work She combined the scientific and the clinical to an unusual degree, she had worked and collaborated with the distinguished staff of the Johns Hopkins Hospital and come in contact with many of the greatest medical minds of her day in America She had done important work both in hospital and in private practice in Baltimore, she had travelled widely and knew the clinics in France, Germany, Sweden, Belgium and America And when the Marie Curie Hospital was started the committee felt that they were fortunate in obtaining her services as radium officer and director of the work , she understood and was able successfully to contend with the difficulties attached to the rather unwilling acceptance of women's work in some quarters of the profession and she won the admiration and respect of her colleagues both male and female wherever her work was known The Marie Curie Hospital owes much to her judgment, scientific mind and independence of thought

Dr Hurdon was not only a scientific worker She was an arresting personality, a stimulating and interesting companion, a good talker interested in what was going on everywhere in the world, and also in the small things of everyday experience, and in the fortunes and misfortunes of her friends When she died she had just finished a treatise on the radiological treatment of cancer which I hope may be published shortly In one of her last letters to me knowing all about her own illness and imminent death, she said she hoped to finish it "in time" And I believe she did

MEDICINE AND THE LAW

Damages for Mental Shock

ONE more case has been added to the series of awards of damages for nervous shock without visible injury At the Norfolk assizes Mrs Englestown was given £450 general damages and £250 special damages in her action against a defendant who had negligently caused an accident which she witnessed The Rev Mr Shead drove his car out of a side road and collided with a lorry driven by Mr Hardy, a haulage contractor Mrs Englestown, walking on the footpath, was not touched by either vehicle , but she complained that her involuntary witnessing of the occurrence had induced a state of collapse There was medical evidence that she was suffering from hysteria , she was afraid of cars , one doctor said that, when he attended her recently, she shrieked at the mention of a motor-car , her condition, he said, was now worse than it was two years ago It was stated that she refused to go into an institution, and yet there was little prospect of her recovery unless there was institutional treatment She had sued both Mr Shead and Mr Hardy The judge found that the former was to blame for the accident , he ordered him to pay the whole of the damages and also Mr Hardy's costs

The modern decisions include Hambrook *v* Stokes (1925), where a mother was held entitled to damages if she could prove that she suffered shock from a reasonable fear of immediate personal injury to herself or her child If she knew that a runaway vehicle was descending a hill on which her child was standing, and if she could prove that she suffered mental shock as the reasonable consequence of the negligence of the defendant who left the vehicle in a dangerous position unattended, then she would recover damages Lord Atkin, then Lord Justice Atkin, was prepared with characteristic courage to extend the liability The negligent person who had failed to look after the vehicle would be liable not merely if shock resulted by reason of a mother's natural anxiety for her child, but even where a bystander felt apprehension for the safety of some third party How much further, one wonders, can the possibilities of emotional disturbance be exploited? A writer in the *Canadian Bar Review* in 1939 cited two instances In Bielitski *v* Obadiak (1922) the Saskatchewan court of appeal allowed a wife to recover damages for shock caused by her having seen the defendant striking her husband This was not far removed from the facts in Hambrook *v* Stokes, but in the second instance the Nebraska supreme court went further In Rosmussen *v* Benson (1938) a dairyman had bought some sacks of bran for his cows from a seller who had forgotten that he treated the bran in one sack with arsenic in order to poison insects The dairyman saw five of his cows die next day and worked himself into such a state of anxiety about his cows and the possible poisoning of his customers that he fell ill and subsequently died The Nebraska court held that the dairyman's executors could recover damages from the negligent seller of bran for the shock and its consequences

In 1939 came an English extension of principle in the case of Owens *v* Liverpool Corporation, where a Liverpool tram negligently collided with a hearse containing a coffin The mother and uncle of the deceased were being driven, with two other relatives, at the head of a funeral procession behind the hearse They were not themselves in any danger , they were not anxious for the safety of any living person , but their emotions were upset by the jolting of the coffin at a moment of natural strain The judges refused to limit the negligent defendant's liability to cases of fear of injury to a human being The Court of Appeal held that the right to damages for mental shock extended to any kind of nervous shock due to a defendant's negligent act On the other hand, in an Australian case in 1939 (Chester *v* Waverley Municipality) a strong court dismissed the claim of a mother in circumstances not unlike those in Hambrook *v* Stokes The municipality had dug a trench in the roadway, rain-water filled it, the town's officials and servants knew that children used to play by the trench but they failed to fence it The mother missed her little boy and went into the street to search for him She saw his body taken from the trench and received a severe shock which developed into illness The Australian court refused to let the mother have damages because, in the opinion of the majority of the judges, her subsequent shock was not reasonably within the contemplation of the municipality as a consequence of its default in leaving the street in a dangerous state Chief Justice Latham insisted that, if it was a question of the extent of a supposed duty to take care, the courts must take into account the probable consequences of the relevant act or omission If one applies this test to the Liverpool tram case or to Mrs Englestown's uncomfortable experience at Norwich, judges and juries will have to say whether a careless driver ought reasonably to have in mind not only the peril he constitutes to motorists and pedestrians but also the risk that potentially hysterical spectators are in the vicinity There are villages where the inhabitants have been said to congregate at dangerous cross-roads on Sunday afternoons in the hope of a little excitement Their experiences may have a cash value

SCOTLAND

CARNEGIE TRUST

At the recent annual meeting of the trust the chairman remarked that it would be idle to speak of future policy at a time when future conditions could only be guessed For 1940–41 the Scottish universities, and those extramural institutions in receipt of grants during 1935–40, would normally receive an advance equal to one-fifth of their quinquennial grant, amounting in all to £50,760 But it was proposed to reduce this grant in the coming year in order to accumulate reserves to meet the heavy calls on the trust's help when peace is restored Many research fellows and scholars who had intimated a suspension of their work would be enabled to resume it at a later date, and in the case of teachers the trustees had arranged to pay half the difference between their stipend and their service pay when called up, the other half being paid by the universities The number of students in receipt of payment of class fees and the amount expended on them had shown an actual increase on 1939–1940, the present expenditure being £54,100 As many new applicants were accepted for the winter session 1940–41 as in each of the previous two years despite the fact that the total number of students had declined This was because the trustees had taken into consideration the rising cost of living and had adopted a more liberal view of students' needs

POOR LAW STIGMA

Dr A S M Macgregor has submitted to his public health committee a scheme for the complete dissociation of Glasgow municipal hospitals from the Poor Law The scheme would extend the principle which has already been adopted for infectious diseases by making the care of sick persons generally the responsibility of the public health department, at present they must apply for poor law relief before admission During 1940 27,500 patients were treated for a variety of illnesses in the general hospitals, all of them by way of the relieving officer, in the same year 18,408 patients were admitted directly and without formality to the fever hospitals Dr Macgregor feels that this differentiation stultifies the usefulness of hospitals whose equipment and specialist services have developed much since they were transferred to the local authority in 1929 Moreover it keeps the public hospitals on a status inferior to that of voluntary hospitals

Public Health

Trichiniasis Further South

During the past month there have been seven known cases of trichiniasis in the urban district of Harpenden, Herts They have been mild, with little or no gastro-intestinal upset, constipation being more common than diarrhœa The symptoms seem to resemble closely those reported from Wolverhampton, with puffiness of the face and muscular pains and weakness The source of infection, which is being inquired into by Prof R T Leiper, has not yet been traced

Infectious Disease in England and Wales

WEEK ENDED FEB 8

Notifications —The following cases of infectious disease were notified during the week smallpox, 0, scarlet fever, 1217, whooping-cough, 3023, diphtheria, 1103, enteric fever, 7, measles (excluding rubella), 15,486, pneumonia (primary or influenzal), 1741, puerperal pyrexia, 138, cerebrospinal fever, 345, poliomyelitis, 10, polio-encephalitis, 1, encephalitis lethargica, 7, dysentery, 168, ophthalmia neonatorum, 82 No case of cholera, plague or typhus fever was notified during the week

Deaths —In 126 great towns there was no death from smallpox, 1 (0) from enteric fever, 3 (0) from scarlet fever, 38 (0) from whooping-cough, 32 (2) from measles, 35 (2) from diphtheria, 39 (4) from diarrhœa and enteritis under 2 years, and 261 (56) from influenza The figures in parentheses are those for London itself

Yarmouth reported the fatal case on enteric fever, Birmingham had 8 deaths from whooping cough, and Liverpool 6 Fatal cases of influenza were scattered over 73 great towns, Liverpool reporting 24 deaths, Blackpool 14, Croydon 8, and no other great town more than 6

The number of stillbirths notified during the week was 198 (corresponding to a rate of 39 per thousand total births), including 5 in London

Incidence of Influenza

The deaths from influenza in the 126 great towns have risen from 53 (8) in the week ended Jan 4 to 69 (9) on Jan 11, 99 (17) on Jan 18, 120 (22) on Jan 25, 176 (40) on Feb 1, and 261 (56) on Feb 8

The return of deaths for the great towns, 261, breaks the sequence of repetitions of the 1929 experience, then following 179 we had 321 The ratio of 261 to 176 is almost the same as the ratio of 176 to 120 so it is very unlikely that a maximum has yet been reached, but it becomes increasingly improbable that the maximum will be of the order of magnitude of that of 1929 and not unduly optimistic to think that it will not exceed that of 1940 The age distribution of deaths is quite normal The detailed figures for London suggest that the maximum of mortality is near, that it may well be in the now current week, and that the maximum of admissions of cases of influenza, pneumonia and bronchitis to hospital is already passed Over half the total deaths still come from the south-eastern area (including London), and it remains to be seen whether mortality in the north will increase at a faster rate

---

The Inconstancy of Milk

Those who purvey milk are to some extent at the mercy of their cattle, and before now dairymen have been prosecuted for adulterating milk with water when the cow was the real culprit The vitamins in milk can vary like other constituents Karl Guggenheim has shown (*J Hyg Camb* 1940, 40, 690) that, in Palestine, season has a great influence over the total vitamin A content of milk, but no certain effect on vitamin C The formed vitamin A remains roughly constant, but the carotene varies with the amount of green fodder eaten In Palestine the carotene and vitamin A of milk correspond to those of American and European milk Where plenty of green fodder is available, as in the valley of Jezreel, there is more vitamin A in the milk Fluctuations in vitamin C, oddly enough, bear little or no relation to the nature of th

versity of Cambridge

t recent examinations the following were successful —

D M R.E.

art I —Manfred Altmann R. D Caton, Arthur Elkeles J E sgow, Grace M Griffith, Max Halberstaedter and P C Phelps

he faculty board of medicine have coöpted Sir Walter gdon-Brown for 1941 They have appointed Dr W L H kworth, Prof H R Dean, F.R S , and Dr G S Graham-ith, F R S , members of the appointments committee for 1–42 , and Dr Graham Smith, Dr R A McCance, Dr B Verney, F R S , and Mr W H Bowen members of the) committee for 1941

he following have been appointed examiners for the l M B for 1941 —

urgery —Mr R. Davies Colley, Mr R M Handfield Jones, Sir ed Webb Johnson, Mr Eric Crook and Mr Julian Taylor following may be called upon to act Mr W H C Romanis, W D Doherty Mr Lancelot Bromley, Mr G T Mullally, Mr Pennell, Mr R M Vick, Mr R H O B Robinson, Mr M F holls, Prof John Morley, Mr W H Hey and Prof Lambert ers

idwifery —Mr Aleck W Bourne, Mr Aubrey Goodwin, Prof J Browne, Dr J R C Canney The following may be called n to act Mr L H W Williams, Mr A J McNair, Dr J D ris Mr Victor Lack, Mr F W Roques Mr R A Brews, Prof nel Dougal Dr A A Gemmell, Mr William Gilliatt and Mr rold Chapple

Medicine —Prof John Ryle Prof J W McNee Dr A E Naish, Charles Wilson, Dr C E Lakin and Dr H Gardiner-Hill e following may be called upon to act Dr. F H. Young, Dr C D Firth Dr J M H Campbell, Dr T L Hardy, Sir Adolphe rahams, Dr Donald Hunter, Dr A G Evans and Prof Crighton mwell

Pharmacology —Dr Verney and Dr McCance The following y be called upon to act Dr Philip Hamill, Dr E C Warner, J C Hoyle, Prof F R Winton, Prof T H Oliver and Dr offrey Bourne

Pathology —Prof Dean and Prof M J Stewart The following y be called upon to act Dr E T C Spooner, Dr E ff Creed, R Williamson and Prof G Payling Wright

yal College of Surgeons of England

A meeting of the council was held on Feb 13 with Sir Hugh tt, the president, in the chair The Hallett prize was esented to Mr J D T Jones of Durham University Mr K Martin of University College Hospital was re elected member of the court of examiners, and Mr Ernest Hey oves representative of the college on the General Medical uncil Dr A P Cawadias was appointed Thomas Vicary turer for 1941

It was decided to recognise the post of second surgical ficer at the Royal Gwent Hospital, Newport, for the six onths surgical practice required of candidates for the final llowship examination

Diplomas of membership, and diplomas in public health d in medical radiology were granted to the candidates med in the report of the comitia of the Royal College of ysicians in our issue of Feb 8 (p 200)

On Monday, Feb 24, Mr R Davies Colley will give the t of the spring course of Arnott Erasmus Wilson demonstrations He will speak on inflammation of bone Other cturers will be Feb 28, Dr A J E Cave, the anatomy of e cervical plexus , March 3 and 10, Surgeon Rear Admiral P G Wakeley, tumours of the alimentary tract , March 7, r Cave, the anatomy of the brachial plexus , March 11, r R Davies Colley, tumours of the breast, and March 14, r Cave, the innervation of the body wall The demonstra ons, which are open to medical practitioners and advanced udents, will be held at the College, Lincoln's Inn Fields, ondon, W C 2, each day at 3 P M

niversity of Sheffield

Mr F W Holdsworth has been appointed honorary cturer in orthopædic surgery

Prof S L Baker (University of Manchester) has been pointed external examiner in pathology and bacteriology

Prof G A Clark has been elected representative of the iversity on the committee to be set up to draft a constitu-on of the proposed regional committee in connexion with e regionalisation Scheme of the British Hospitals Associa-on and the Nuffield Provincial Hospitals Trust

Dr R E Lane has been appointed lecturer in medicine the University of Manchester

Pharmaceutical Students and the Army

The Pharmaceutical Society is making representations to the Ministry of Health concerning the future supply of pharmaceutical students who are at present reserved from military service when they have completed two years of training The wording of the reservation prevents newcomers into the pharmaceutical calling from securing reservation before they are qualified, and after students of the present generation have passed their examinations there may be only women entering pharmacy It is hoped to secure a modification of the schedule so as to enable a reasonable annual intake of students to be maintained

Lieutenant N B Walker, M B Durh , R A M C , and Lieutenant A L Karstaedt, M B Cape Town, R A M C , who were previously reported missing are now posted as prisoners of war

The M B E has been awarded to Lieutenant Robert Horton, M B Lond , R A M C , and the George Medal to Lieutenant John Monks, M B Manc , R A M C , and Dr William Walton, medical officer of health for West Bromwich

The following meetings of the Davyhulme Military Hospital Medical Society have been fixed —

Feb 27, Major F I Evans, who will speak on burns, March 13, Prof Crighton Bramwell, effort syndrome , March 27, Prof Harry Platt, deformities of the hands and feet , and April 4, Major H B Jones, venereal disease in the Army and its treatment The meetings will begin at 3 P M and medical men or women in any of the services (including civilian) will be welcomed

On Feb 20 Lord Horder, president of the Chartered Society of Massage and Medical Gymnastics, presented to the war organisation of The British Red Cross Society and the Order of St John of Jerusalem a mobile physiotherapy unit for the treatment of men in the forces

The unit, which is to be the first of several, will be staffed by qualified members of the society, and it contains apparatus for giving electrical and light treatments, such as galvanism, faradism, infra red rays, radiant heat, ultra violet light, and paraffin wax baths The apparatus and its accessories are mounted on four trolleys which can be wheeled out of the van and into each hospital

Births, Marriages and Deaths

BIRTHS

Cathie —On Feb 13, the wife of Major Ian Cathie, R A M C , of Leigh, near Reigate—a son

Davidson —On Feb 5, at Newcastle upon-Tyne, the wife of Dr Whately Davidson—a daughter

Leader —On Feb 7, the wife of Dr Reginald Leader, of Erith, Kent—a daughter

Mills —On Feb 11, at Ramsbury, Wilts, the wife of Dr W. T Mills—a son

Southward —On Feb 8, in Glasgow, the wife of Lieut Ralph Southward R.A M C —a son

Stevens —On Feb 12, in Cairo, the wife of Major C P Stevens, R A.M C —a son

MARRIAGES

Bacon—Wrightson —On Feb 15 at York, Aidan Henry Bacon, M B to Gwendoline Joyce Wrightson

Gallie—Eustace.—On Feb 5, at Sliema, Malta John Ross Gallie, M B , lieutenant, R.A M C , to Edythe Madeline Eustace

Jack—Weeks —On Feb 10, at Abbasia, Cairo, Ewen Alistair Jack, F R C.S E , major, R.A M C to Vivien Mary Weeks

Pye Smith—Ford —On Feb 15 at Ilkley, Edward John Pye-Smith M B , captain R A M C , to Mary Audrey Ford

Stewart—Lochhead —On Feb 12 at Ipoh Perak, William Muir Stewart, M B , captain, R.A.M C , to Helen Cargill Lochhead

White—Arnould —On Feb 11, in London Michael William Langtry White, M R C S , to Mary Seton Arnould

DEATHS

Bogle —On Feb 13 at Cheltenham, James Linton Bogle, M D Edin , late of Villa Vaniglia Bordighera aged 89

Bulloch —On Feb 11, William Bulloch, M D , LL D Aberd , F R S , aged 72

Burnside —On Feb 17, at Paisley, Eustace Augustus Burnside, M R C S Colonel A.M S (ret), Knight of the Order of St John of Jerusalem, aged 80

Gray —On Feb 18 at Hindhead, Sarah Gray, F R.C S I aged 81

Kinsey-Taylor.—On Feb 12 Alfred Ernest Kinsey Taylor, M B Lond , F R.C S of Farnham Royal, Bucks

Starkie —On Feb 11 at Watford, Richard Francis Starkie, M D R.U I , aged 88

Ticehurst —On Feb 17 at Hastings, Claud Buchanan Ticehurst, B Chir Camb , F R G S , of Appledore Kent

Notes, Comments and Abstracts

OWL'S-EYE VIEW OF DIET

IN his Honyman Gillespie lecture delivered on Feb 13 Dr C P Stewart spoke on nutritional factors in dark adaptation The term has been used to cover not only the adaptation of the photo-receptivity of the retina, but also the changes occurring in the nerves to the visual centre A purely chemical process is involved in photo-receptivity

Bright light breaks down the visual purple found in the rods while it is synthesised in the dark The brighter the light the greater the rate of destruction Visual purple is manufactured in the retina from several precursors, one of which is vitamin A Bleaching of the pigment results in the reformation of the vitamin All methods of investigation depend on exposing the eyes to a bright light and then noting how long it takes them to appreciate varying low intensities of light Such investigations show that dark adaptation not only by the rods but also by the cones must be taken into consideration Cone adaptation is carried out by a pigment similar to visual purple which may also be synthesised from vitamin A Changes in the neural elements and the nerves must also be considered, and possibly visual acuity as well It has long been known that cod-liver oil and liver are useful in the treatment of night-blindness Surveys of the population by Jeans showed that 20% had subnormal dark adaptation correlated to a deficiency of vitamin A in the diet Within 3 to 4 days of being put on a vitamin A-free diet subjects showed impaired dark adaptation, and after 4 to 5 weeks classical night-blindness might be present The rate of return to normal under the influence of vitamin A is much slower than the depreciation due to the lack of it Later research has refuted claims that there is a high degree of correlation between the dark adaptation and the vitamin-A content of the body All that can be stated is that when dark adaptation is normal then the vitamin-A content is normal, but when dark adaptation is abnormal other factors such as abnormalities of the retina and defects in the neural elements and nerve-fibres must be taken into consideration as well as a possible defect in the vitamin supply Vitamin C also plays a part in the chemical reactions, for it has been shown that the addition of ascorbic acid to the diet improves dark adaptation This action is different from the action of vitamin A, for it can be shown that further improvement takes place although a full supplement of vitamin A has already been given The metabolism of the retina simulates very closely that of brain tissue in general Some fractions of the B complex are necessary for proper metabolic function—namely, aneurine, riboflavin, and nicotinic acid The evidence is still incomplete, but recent work has shown that some people with subnormal dark adaptation who have failed to respond to either vitamin A or C have responded to the addition of riboflavin to the diet Other factors affecting dark adaptation are age and changes in oxygen tension The older the subject the higher the light threshold and the longer the time taken for the eye to become dark adapted Reduction of oxygen tension corresponding to a height of 8,000 feet produces definite lowering of dark adaptation, while at an oxygen tension representing 18,000 feet there is severe night-blindness The effect of reduced oxygen tension appears to be on a different mechanism than that influenced by vitamin A With vitamin-A deficiency the rods are affected but the cones are not and the time factor is delayed In reduced oxygen tension the time factor is unchanged, but the dark adaptation of the rods and the cones are affected equally

ASTLEY COOPER

Thomas Wakley would turn in his grave if the centenary of his death on Feb 12, 1841, were allowed to pass without some mention of his association with THE LANCET in its early days Our first number, for Oct 5, 1823, opened with the report of a lecture by Astley Cooper announced as follows

> " and as the Lectures of Sir Astley Cooper, on the theory and practice of Surgery, are probably the best of the kind delivered in Europe, we have commenced our undertaking with the introductory address of that distinguished professor given in the theatre of St Thomas's Hospital on Wednesday evening last "

Unlike Abernethy who followed him as THE LANCET's chief attraction, Astley Cooper did not resent the publication of his lectures, though he felt himself " disgraced and degraded by his name forever appearin in the diurnal press," which then as now sometimes found good news value in medical reports This led to a call on Wakley and the threat of an injunction In his " Life and Times of Thomas Wakley " Sprigge recounts how Astley Cooper obtained admission in the characte of a patient, and caught Wakley, who at the time believed the secret of his editorship to be inviolate, in the act of correcting a proof of one of the lectures in question. " Never did a small check serve a man to better purpo than did Sir Astley Cooper's little ' score '—there is no other word—serve Wakley The great baronet was so pleased at the success of the rather transparent ruse that had gained him entrance and at the sight of Wakley obvious discomfiture when he found his anonymity gone that any wrath he might have been cherishing was di solved in hearty laughter " Wakley gave an assurance that Astley Cooper's name would be omitted from futur reports and peace was made Astley Cooper neverthe less strongly opposed the publication of operations as being likely to prove destructive to the reputation of the rising generation of surgeons, but he stuck loyally to his pact and took no part in the later wrangling betwee lecturers and THE LANCET as to whether the publicatio of a lecture infringed the author's copyright

On Monday, Feb 24, at 2 P M, Dr E Wilfred Fish wi address the odontology section of the Royal Society o Medicine on benign neoplasia of tooth and bone On Feb at 2 30 P M at a combined meeting of the sections of medici and ophthalmology Dr W D Wykeham Brooks and Colo F A Juler will open a discussion on iridocyclitis On th same day at the same time Dr C P Symonds is giving h presidential address to the section of psychiatry On Feb 27, at 3 30 P M the section of urology will hold a clinic pathological meeting at which specimens will be shown

On Jan 24 the state department of health for New York began the free distribution of sulphapyridine in an effort further to control pneumonia in the state and to help patient who are too poor to try it The drug is being distributed fo the use of registered doctors and hospitals, and a list of supp stations designated for this purpose has been drawn up Th drug will only be obtained on the request of a physician f the treatment of a specific case

Appointments

BREWER, H L, M B Melb, F R C S R S O at St John's Hos pital, Lewisham

ANAEROBIC INFECTIONS AND GAS GANGRENE[1]

By G. T Mullally, M C M S Lond F R C S
SURGEON TO WESTMINSTER HOSPITAL

It is not yet sufficiently realised that just as septicæmia is a sequel or complication of pyogenic infection so gas gangrene is an infrequent complication of anaerobic infection. Two related conditions must therefore be defined at the outset infection by gas-forming anaerobes; and true gas gangrene.

INFECTION BY GAS-FORMING ANAEROBES

There is a group of spore-bearing anaerobic organisms of which *Clostridium welchii* and *Cl. septique* are the most often met which are commonly found in all types of lacerated wounds. The organisms or their spores are constantly present in cultivated soil and in clothing made from wool or skins. The infection is likely to be more heavy in lacerations received in the highly cultivated lands of Western Europe, and in those parts of the world where wool and skins are necessary for protection from cold, than in the deserts of North Africa or in warm climates or seasons when cotton clothing is sufficient. The infection will also tend to be heavier when the wound is produced by direct external violence than when it is produced by internal violence, as in a compound fracture resulting from indirect force. It will also be heavier when the wound is produced by irregular missiles, such as bomb or shell fragments or broken bullets, than when the wounding agent is smooth like a bullet or a bayonet. The irregular missile will certainly carry in some clothing containing the organisms.

It is safe to assume that all recent wounds seen in England which have been caused by shell or bomb fragments are infected by gas-forming anaerobes. These organisms will grow and spread rapidly but at first only on dead or almost dead tissue. They produce a greyish film on the wound surface from which escapes a small amount of thin dirty exudate with an unpleasant smell often containing small bubbles of gas. These changes in the wound surface occur very rapidly and are usually well established within twenty-four hours of the injury—that is they appear much more rapidly than the familiar changes due to pyogenic infection. These first changes are not accompanied by gross swelling or hyperæmia of the wounded part nor is there any characteristic general reaction.

If the wound is associated with much laceration and bruising of the surrounding tissues these rapidly change colour and become green and black much brownish discharge appears gas bubbles freely from the blackened sloughs and the wound smells abominably. There is swelling of the surrounding tissues and often a little crepitation from gas under the skin. The wound is not unduly painful; the temperature and pulse-rate are moderately raised and the patient looks and feels ill. Such a wound under any or no treatment will shortly produce laudable pus from the action of the ordinary pyogenic organisms the sloughs will separate leaving weak pale granulations bathed in pus and at the end of a fortnight it will be covered by healthy granulation and well on the way to healing. In other words, the anaerobic infection has produced some interesting phenomena in the first forty-eight hours but has not obviously interfered with the normal processes of inflammation and repair. Indeed gas infection is an interesting but harmless feature of most lacerated wounds. It would not be worthy of special mention and study were it not that in a small minority of cases it is liable to develop the rapidly fatal and almost untreatable complication which we know as gas gangrene.

GAS GANGRENE

Gas gangrene is an *acute spreading gangrene* characterised by the production of large amounts of gas in the tissues and by a profound toxæmia. The natural termination of the disease is death from toxæmia or from a general invasion of the body by the causal organisms. It is an infrequent complication of the infection of wounds by certain spore-bearing anaerobes of which *Cl. welchii* and *Cl. septique* are the most important. Within a time varying from six hours to four days but usually in the second twenty-four hours after the injury, the wound becomes abnormally painful and the surrounding tissues become swollen and tense. At the same time there is a steep rise in the pulse-rate and sometimes a rise in temperature, though this is not great as a rule and is often absent. These are prodromal signs gangrene threatens.

If nothing is done to abort the disease the pain will continue for a variable time according to the severity and acuteness of the attack and will often cease quite suddenly. The pulse-rate continues to rise to 140 or even 160 but is the pulse of fever and not the running pulse of shock or collapse. The patient who is at first alert but anxious and distressed by the pain and discomfort becomes conscious of a change for the better. He is often excited and talkative, assuring himself and everyone how much better he is; he becomes restless and thirsty and in the later stages vomits incessantly. In contrast with his euphoria, his complexion—which in the early stages shows the flush of fever—now has a muddy pallor which obviously presages death. Mild jaundice is common in the last stages and is often seen soon after the onset of the disease. A coma of exhaustion usually precedes death.

Locally the tense and swollen limb becomes yet more tense and swollen; crepitations from gas can be felt under the skin, which becomes white and waxy. The swelling and crepitation begin to advance rapidly, traversing the thigh from knee to groin in two hours or less. They do not stop at the junction of the limb with the trunk but go on inexorably, not even ceasing with the patient's death. At first the tense white skin is obviously alive whatever may be the condition of the underlying tissues, but as time passes it too dies. The first sign is a brown discoloration from hæmolysis. This is only a warning and skin so stained is probably viable but when purplish discoloration appears the skin is dead. The smell or the gas escaping from the wound are only evidences of gas infection and not necessarily of serious importance. Smell and gas do not make gas gangrene, but may presage its arrival. The diagnosis is made on two main features severe and progressive toxæmia as shown by rapid pulse, restlessness euphoria and vomiting and increased swelling and tension in the wound area with evidence of gas in the tissues.

The warning that gas gangrene is imminent is given by the combination of increase of pain and tension in the wound and a steep rise in the pulse-rate. A wounded man once he is settled comfortably in bed should not be conscious of severe pain. If he is in severe pain something is wrongly arranged or some change—such as hæmorrhage—is occurring. If a patient who has been reasonably comfortable complains of pain and becomes restless always ask yourself if he is threatened with gas gangrene, and don't rest until you have satisfied yourself on this point. There are few conditions in which a few hours may be so vital. Infection with gas-forming anaerobes is a common almost universal feature of all war wounds; gas gangrene is an infrequent complication of such infection. Infection with gas-forming anaerobes needs no specific treatment except that directed to the prevention of gas gangrene.

FACTORS IN THE DEVELOPMENT OF GAS GANGRENE

The wounds which develop gas gangrene are ones involving muscle, but not all muscle wounds go on to gas gangrene. Generally speaking the larger the amount of muscle damaged the greater the danger of gas gangrene, but this is not the whole story. Big open lacerations of the thigh or buttock may severely damage a pound or more of muscle, and this great devitalised mass will show all the phenomena of infection with gas-forming anaerobes in their most obvious form. Much smell much gas colour changes in the muscle from brick

---

6131

red to green and black, will all be obvious, but the patient, although seriously ill from the severity of the infection and the suppuration, will not be in any danger of gas gangrene. So the disease is not due simply to infection of damaged muscle with gas-forming anaerobes; there must be some other factor.

But if a fragment of shell, penetrating the buttock through a small hole in the skin, grossly lacerates the muscles without disturbing the overlying fat and skin gas gangrene is very likely to develop; here a large mass of lacerated and gas-infected muscle is enclosed so that when swelling occurs the local tension is greatly raised. Perhaps the important cause is not the injury to muscle but the tension. The apparent liability of wounds of muscle to develop gangrene may arise from the fact that almost all severe wounds involve much muscle and that the real cause of the disease is the retention of the infected tissues under pressure. There is evidence to support this view. Infection of a large hæmothorax with gas-forming anaerobes may go on to a fulminating attack of gas gangrene and similar infection of the retroperitoneal tissues may give rise to an inevitably fatal spreading cellulitis and gangrene. In each of these cases we have gas gangrene starting in dead or damaged tissue other than muscle. It is clear, therefore, that injury to muscle is not an essential feature of the disease. But it will not do to ascribe the disease merely to raised tension at the site of the wounds. In penetrating wounds of the brain it is a common thing to find that when the hole in the bone and the dura is enlarged gas and decomposing brain escape with such force as to show they have been retained under considerable pressure. In spite of this I have never, in my experience of many hundreds of brain wounds, seen gas gangrene follow. In fatal cases of gas gangrene beginning elsewhere and terminating in a blood infection I have seen the brain at autopsy full of gas bubbles. There is thus no inherent antagonism between brain tissue and the anaerobes, and it seems to follow that retention of the infected tissues under pressure is not by itself enough to lead to gas gangrene.

Infection by gas-forming organisms of a large mass of tissue, either grossly damaged by the missile or—as in the case of blood in a hæmothorax or in the retroperitoneal space—cut off from the defensive mechanisms of the body, is very liable to go on to gas gangrene if free drainage to the exterior is prevented. The danger scarcely exists if the amount of damaged tissue so retained, as in brain wounds, is small. Another group of cases illustrates these points dramatically—wounds in which the main vessel of a limb is divided so that the part distal to the wound is threatened with simple gangrene. In these gas gangrene is almost certain, and every hour that passes without treatment makes the disease more certain. The wound need not be large—a tiny fragment is as lethal as several ounces of metal. Here we have the large mass of ischæmic tissue retained under the intact skin.

The factors then which make for the development of gas gangrene in some wounds are: a large mass of damaged and devitalised tissue confined in such a way that the products of the infection cannot escape, and must be absorbed. This explanation does not, at first sight, cover all the cases seen. Gangrene often occurs in comparatively slight wounds of the calf and thigh muscles, in which the total amount of laceration must be small. Wounds of this type will only develop gas gangrene if the damaged tissue is muscle. Small wounds of skin or subcutaneous tissue or bone or brain are not dangerous in this regard although the infecting organisms will grow freely in them.

MUSCLE

Does the anatomy of muscle explain the appearance of gas gangrene in comparatively unimportant wounds? Muscle is an aggregation of long fragile fibres enclosed in a strong fascial sheath. The fibrous inelastic sheath closely invests the fleshy mass, is attached to the tendon or bone in which the muscle ends and often gives attachment to many of the muscle-fibres. In the limbs each group of muscles is enclosed by an outer sheath of strong fascia, and then the deep fascia of the limb forms a sheath enveloping all the muscles together. The blood supply is derived in the trunk from small branches from many sources, but in the limbs many of the muscles are supplied by one or two main branches, which have a very poor anastomosis with vessels outside the sheath. Consequently any interference with the main blood supply of a limb muscle is liable to cause a dangerous ischæmia.

When a small fragment of bomb or shell enters the calf or thigh it makes a small hole in the skin which may or may not gape, then a large hole with soft ill defined walls in the subcutaneous fat; it then pierces the deep fascia, through a hole just large enough to admit it and no larger, and with sharp, rigid, inelastic edges; finally it pierces the muscle sheath and enters the muscle tissue. So far it has been traversing passive tissues, now it strikes an active tissue which responds to stimulation by a violent contraction. This reflex contraction pulls the damaged muscle-fibres widely apart, with the formation of a relatively large ragged cavity.

The ordinary reactionary swelling and hæmorrhage in response to the injury takes place inside the muscle sheath. Escape of the contained blood and fluid is often prevented by the shape and narrowness of the wound track or by prolapse of torn muscle or fat into the narrow fascial opening. So that there is now a small mass of infected material enclosed in the limb. Gas forming anaerobes become active and multiply rapidly in the walls of the ragged cavity and in the contained blood and debris; swelling of the muscle increases and gas is formed. Shortly the muscle sheath is completely filled and the cycle of strangulation with which we are familiar in so many inflammatory diseases begins to occur inside the muscle sheath. The venous return is interfered with, more swelling and œdema follow, more obstruction results, and before long what was a minor injury to the muscle has led to gross interference with the nutrition of a large part of it. Circumstances favouring the development of gas gangrene are thus produced.

TREATMENT

I have said nothing of the bacteriology and biochemical aspect of the problem partly from ignorance, but chiefly because, as I understand it, nothing has yet emerged which helps in the practical management of the disease.

The aim of treatment is to prevent the development of the disease, or, if this cannot be done, to arrest it with as little damage to the patient as is possible. The problem of gas gangrene would not arise if all wounds could be properly excised with three to six hours of infliction. A successful excision of a recent wound will ensure that the anaerobic infection is reduced to a minimum and that no considerable mass of material is left in which the organisms can prepare for an assault on the undamaged tissues. But only a minority of important wounds lend themselves to satisfactory excision. The patient may not reach the surgeon sufficiently early; his general condition may preclude operation for a good many hours, the multiplicity of his wounds may mean that the full operation would take two hours, or even more; the total number of patients needing attention may be such that only those measures which are essential can be taken for each one.

With patients in whom infection with gas forming anaerobes is already established or presumed we must aim at rendering the infection innocuous. The first step is to enlarge the wound in such a way that there is free drainage into the deepest recesses. The skin wound should be extended by adequate incisions, preferably parallel to the long axis of the limb; these incisions should go through the superficial fat as far as the deep fascia. The wound in the deep fascia should then be enlarged in the same directions, and if necessary (and it often is) the fascia should be divided transversely also so that the tortuosities of the wound track are more clearly visible and the tension is more adequately relieved. Next, the hole in the underlying muscle sheath must be similarly enlarged, and then the walls of the wound in the muscle itself cut away freely until healthy muscle is exposed. This needs care because the fibres may retract unequally and deep pockets may be found in the walls of the wound, the openings into which must be enlarged freely. The wound track should be followed through from muscle to muscle if necessary, the same care being used, whenever a fascial layer is encountered, to make an adequate opening.

---

2 See Campbell, J and Pennefather, C M *Lancet*, 1919, 1, 294

It will often not be practicable to pursue this ideal pening up to the full depths of a small wound in, say, the ig muscles of the thigh, the damage done would be ncommensurate with the risk that we are trying to essen In these cases, however, the real danger comes rom the small holes in the inextensible fascial sheaths, nd these holes should be freely enlarged whenever and wherever they are encountered We must watch out or the nerves running to the muscles and never divide vessels going into a muscle Division of such a vessel may provide just that mass of dead or damaged tissue we are trying to get rid of From the limited angle of nfection with gas-forming anaerobes and gas gangrene t matters little what is done with the wound once it has been adequately opened up Probably some form of oose pack is best

Treatment on these lines will be sufficient for wounds of muscle seen before any evidence that gas gangrene is hreatened If the case cannot be dealt with until pain and swelling and rise in pulse-rate have occurred, the same approach should be made, but on more generous ines, until the damaged muscle is reached There will be much more smell, gas bubbles will be seen, and the muscle round the wound track will be firm and friable of a brick-red colour, and will not contract on stimulation All this muscle must be freely cut away until healthy bleeding and contracting muscle is reached It may be necessary to resect a whole muscle belly before one can be satisfied that safety has been ensured If faced with the next stage of actively spreading gangrene, do not rush at once to amputate Ask yourself if it is possible to get rid of the gangrenous mass by a local excision of a muscle, or a group of muscles It may be possible to save a limb by sacrificing the soleus and gastrocnemii, or the hamstrings In doubtful cases there is neither danger nor objection to large exploratory incisions into the affected area It is important to remember that the upper limit of the gas is not related closely to the upper limit of the gangrene but often precedes it by many inches, conversely, the gangrene of muscle always extends to a higher level than that of the skin If amputation must be done it is usually possible and advisable to fashion skin flaps, which should be long to allow for excessive retraction If on dividing the muscles it is found that one or more is already gangrenous at the site of section, do not change your plan—finish the amputation and then split your stump widely and excise the dead muscle Never sew the flaps together, just pack the wound with gauze and bandage it firmly

As far as I am aware, there is as yet no serious evidence that anti-gas-gangrene serum and sulphanilamide have any effect Much that has been ascribed to them seems to be based on ignorance of the normal course of these infections and of the effects of surgical treatment As to X rays, I would hesitate to use an empirical method in a disease so dangerous and rapid, I will wait until good evidence of its efficacy is produced

ELIMINATION OF STREPTOCOCCI FROM SUPERFICIAL WOUNDS

BY SULPHANILAMIDE POWDER

By Leonard Colebrook, M B Lond
COLONEL, R A M C CONSULTANT BACTERIOLOGIST AND
A E Francis, M D Lond, M R C P
MAJOR, R A M C

The introduction of sulphamido-chrysoidine (red prontosil) by Domagk in 1935 and of *p*-amino-benzene-sulphonamide (sulphanilamide) by M and Mme Trefouel, Nitti and Bovet (1935) attracted world-wide attention, because these compounds seemed to bring us for the first time within sight of an "internal antiseptic," that is one which would control bacterial infection by way of the blood-stream In the earliest clinical trials in this country it was observed that the hæmolytic streptococci were not killed off completely in the local focus, for they could often be cultivated from the lochial discharges for two or three weeks after a patient's recovery from puerperal fever (Colebrook and Kenny 1936) Similarly they were found to persist in the tonsils after treatment of tonsillitis or scarlet fever Further, Domagk and other German authors laid stress on the fact that red prontosil had little or no direct bactericidal or bacteriostatic effect on hæmolytic streptococci

These considerations made it appear unlikely that the local application of the new drugs to infected wounds would have much effect Later, however, when it became clear that red prontosil was converted into sulphanilamide in the body (Trefouel et al, 1935, Fuller 1937), and that this latter substance had a considerable bactericidal and bacteriostatic effect on hæmolytic streptococci in vitro, even when no cellular elements were present (Colebrook, Buttle and O'Meara 1936, Hoare, 1938, Fuller, Colebrook and Maxted 1940), the possibility that the local application of the drug might be beneficial began to attract attention Purdie and Irx (1937) were the first in this country, so far as we are aware, to report the powdering of a wound infected with hæmolytic streptococci In order to obtain the maximal therapeutic effect these authors gave sulphanilamide by mouth as well as locally, and there was therefore some doubt as to how much of the striking clinical result was due to the local application During the last few months the opportunity has arisen to investigate the effect of local applications of sulphanilamide (and sulphathiazole) on a number of superficial wounds in the maxillo-facial unit of Park Prewett Hospital (E M S) at Basingstoke

In the investigation 35 patients with 62 wounds were followed through for several weeks All of them were infected with hæmolytic streptococci, 55 wounds yielding cultures of Lancefield's group A, 9 of group G, and 1 of group C In 1 case the original infection was a streptococcus of Lancefield's group D, this case subsequently became infected with group-A streptococci In 3 cases an original infection with streptococci of group A was replaced, after treatment with sulphanilamide, by hæmolytic streptococci of group D. The great majority (32 patients) received sulphanilamide locally only, and none by mouth Swabs were taken from the wounds usually 24 hours after the last application of sulphanilamide powder In order to exclude the possibility that the absence of streptococci in cultures was due to transfer of a trace of the drug on the swab, the latter was sometimes inoculated into 10 c cm of blood broth from which subcultures were made on blood agar They never gave a positive result where the direct plate culture was negative In other cases negative swabs were planted on blood agar containing 1/500,000 gentian violet (Garrod 1933), in order to ascertain that a few streptococci were not overgrown by an abundant growth of staphylococci

METHOD OF APPLICATION

It was found essential, before beginning treatment, to remove sloughs coagulated exudate, dried pus and remains of tan This was effected by saline baths In some cases eusol dressings were found to be of assistance Wounds were usually dressed once daily After removal of the old dressings, which were sprayed with sterile saline to facilitate removal and minimise trauma in cases not receiving saline baths, and after completion of the wound toilet, finely powdered sulphanilamide was insufflated on the wound, and over grafts if these were present, until the appearance resembled a hoar-frost No advantage was found from heavier powdering Tulle gras was then applied and gauze, well moistened with saline, covered this In order to retain moisture the gauze was covered in turn by a considerably larger sheet of jaconet or oiled silk, and a firm bandage applied We would emphasise the importance of this retention of moisture and of applying the powder to the wound surface before a thin film of dried exudate has formed on it—often a matter of only two or three minutes exposure In several instances when attention was not paid to these details streptococci persisted longer than usual on the wounds

When the next dressing was performed 24 hours later the sulphanilamide was found to be completely dissolved on all raw areas though it was still clearly visible on the surface of grafts and on the surrounding skin Solution was not always complete in a few cases in which the wounds were examined after 4 or 6 hours

In some cases sulphathiazole was used It was found to be almost completely undissolved after 24 hours, but most of it had disappeared if left for 48 hours It appears to have been less effective than sulphanilamide in these circumstances against *Streptococcus pyogenes*, but has freed a small number of wounds of *Pseudomonas pyocyanea* and *Proteus* Sulphanilamide has not been successful with the latter organisms

RESULTS

Group-A infections—In 21 cases with 33 wounds infected with *Streptococcus pyogenes* the local application of sulphanilamide powder resulted in the permanent disappearance of the microbes In 3 cases with 10 sulphanilamide was also given by mouth, and in these the streptococci also disappeared In 4 cases a recrudescence of infection followed grafting operations which were carried out within ten days of obtaining the first negative swab from the wounds concerned Owing to the procedure then followed the wounds were not dressed for several days, and powdering could not be continued The streptococci were of the same type before and after grafting in each case One other case should probably be classed under this heading, but the type of streptococcus originally present is not known The infection reappeared in one case four days after the discontinuance of powdering Another patient who returned to hospital a month after discharge with a small ulcer on a grafted area was also found to be harbouring hæmolytic streptococci in this ulcer In all these cases the infection responded to a further course of treatment, with the exception of the last, who had to leave hospital before treatment could be started, for urgent domestic reasons

Group-C infections—In one case a wound was freed of group-C streptococci and healed uneventfully

Group-G infections—In one case these streptococci disappeared with local treatment only, in another with local and simultaneous oral therapy, and in a third case, unsuitable for local therapy (compound fracture of the mandible), with oral sulphanilamide only

Group-D infections—In 4 cases this streptococcus has been found to resist local treatment with sulphanilamide

ILLUSTRATIVE CASE-RECORDS

The signs +, ++ and +++ indicate the presence and abundance of hæmolytic streptococci in culture, the sign − indicates a negative culture, Sm or Stz 1/d indicate the local application of sulphanilamide or sulphathiazole powder respectively once daily

CASE 1—Excision of rhinophyma, Sept 20, 1940 Two unhealed ulcers on nose

,, 28	Few Group A, type 12		

Since no *Strep pyogenes* were found in the throats of patient or the nursing staff, and since no other patient in same ward was harbouring a streptococcus of identical t it is thought that the organism, which was *resistant* to t ment, remained in the depths of the granulation tissue final result, after two failures, is satisfactory

DISCUSSION

In view of the well-recognised tendency for hæmol streptococci to persist in open wounds, it seems hi probable that their prompt disappearance from so m wounds in this series after the beginning of local tr ment with sulphanilamide was in fact due to the c and not to coincidence

Dusting with sulphanilamide certainly had no adv effect on the healing process, indeed, in the majo healing seemed to be much accelerated when the stre cocci disappeared In a few cases the actual area traced on sterile Cellophane at intervals and meas ments of the area were made by planimeter * such case showed a reduction from 17 6 to 10 7 sq cm 5 days, and another from 5 2 to 2 0 sq cm in 8 d Further observations of this kind are required If t confirm the impression of rapid healing we have obta hitherto, the question will arise as to whether the accel tion was entirely attributable to the elimination of streptococci, or was perhaps due in part to some stimu action of sulphanilamide

The results obtained on superficial wounds with l exudate do not justify the assumption that sulpha amide introduced into a freely suppurating deep wo ll also get rid of streptococci, or even inhibit their e growth Fleming (1940) and Macleod (1940) have own that pus usually contains some factor (? products proteolytic digestion) which neutralises the bactericidal d bacteriostatic effects of sulphanilamide on strepto cci in vitro It may be that this factor, operating a suppurating wound will prevent the elimination of reptococci On the other hand it may sometimes happen at a strong solution of the drug in such a wound ll overcome the inhibitory effect of the pus that can ly be determined by observation of a number of cases

---

* For these measurements we are indebted to Mr C W Burt Basingstoke

It is also to be expected that even on superficial ounds with little exudate sulphanilamide will somemes fail to eliminate hæmolytic streptococci, and that ese may reappear in the wound This may be due some cases to a relative insensitiveness of the streptoccus to the drug (Such relative insensitiveness has en demonstrated in vitro with a few group A strains e Hoare 1939) In other cases it may be due to refection from a deep focus to which the sulphanilamide es not gain access Reinfection may also sometimes e due to the persistence of streptococci on the skin ound the powdered wound owing to lack of fluid in hich the sulphanilamide can dissolve We are indebted Prof A. A. Miles for calling our attention to this ssibility He has himself observed such persistence the skin after disappearance of hæmolytic strepto cci from the actual wound We have confirmed this servation in a few instances It is to be noted here at we have found hæmolytic streptococci of Lancefield's oup D to be entirely resistant to sulphanilamide when pplied to wounds infected with these microbes, just as ey are resistant in the urinary tract

The ability to change the bacterial flora of superficial ounds at will—or at least to eliminate certain undesirble types—is likely to prove of considerable value ur experience suggests that the removal of hæmolytic reptococci will greatly accelerate healing, it will also nable plastic and orthopædic operations to be underaken with more assurance of success than in the past f, in the future, we can eliminate *Ps pyocyanea* and *proteus* as well the scope and value of skin grafting perations will also be greatly increased It may be at one of the potent antibacterial compounds produced y moulds or certain bacteria—e g, penicillin or "gramiidin"—will achieve this result

In the early treatment of burns too we may hope for aluable help, since streptococcus infections have in the ast been responsible for most of the tissue destruction and not infrequently for generalised infection) as well s for slow healing and the distressing contractures ssociated with it A recent experience with a group of severe burns (which will be reported elsewhere) suggests hat by local chemotherapy these infections can often e terminated in a few days and rapid healing secured

Yet another result may be expected—perhaps the ost important in the long run The elimination of æmolytic streptococci from many open wounds must nevitably diminish the chances of cross-infection in urgical wards There can be little doubt that the dissemination of organisms occurs chiefly in four ways— y dust, by faulty surgical technique, by the social ontacts of patients in the wards, and by droplets from ersons with an infected throat or nose The first three f these channels of infection will be effectively blocked n proportion as we can eliminate streptococci from our pen wounds Our experience at Park Prewett Hospital ffords a striking illustration of how the "streptococcus oncentration" in surgical wards may be affected by hese means When this investigation began no less han 73% of all the open wounds in the maxillo-facial nit were infected with hæmolytic streptococci Six eeks later the proportion had fallen to 20% infected ith all groups of hæmolytic streptococci or 12% infected ith group-A streptococci Although certain other easures—e g, segregation of cases, prophylactic dministration of sulphanilamide before operation and a tricter ward ritual—had been put into operation during his period, it is probable that the use of sulphanilamide owder was chiefly responsible for the change

SUMMARY

The effect of applying sulphanilamide powder to 62 uperficial wounds infected with hæmolytic streptococci has been investigated In 5 patients with 10 wounds the drug was given by mouth at the same time Hæmolytic streptococci usually disappeared from the wounds within 3 or 4 days and did not reappear Infections with hæmolytic group-D proved resistant to local treatment.

Neither sulphanilamide nor sulphathiazole had consistent effects on the staphylococci *B proteus* or *Ps pyocyanea* which were also present in many of the wounds

Acknowledgments are made to Sir Harold Gillies and the medical officers and sisters of the unit at Basingstoke for their collaboration in the work, to Dr C W Morley in charge of the laboratory for his help in carrying it out to Dr F Griffith and Dr Dora Colebrook of the Research Laboratory for Streptococcus Infections in London (Medical Research Council) for typing and grouping the many strains of streptococci and to Dr N I Connolly superintendent of Park Prewett Hospital, for his consent to publication

A HUNDRED CASES OF BREECH PRESENTATION

BY

ALAN GAIRDNER
B M OXFD F R C S

MARGARET HADLEY JACKSON
M B LOND D R C O G

L N JACKSON, M C, D M OXFD

IDEALLY, breech delivery ought to be extremely rare In practice attempts at version, particularly in primigravidæ, often fail and choice has then to be made between vaginal delivery by the breech or delivery by cæsarean section It seemed to us worth while to collect a number of cases of breech presentation treated in hospital and private practice and to consider the results of various methods Under infant mortality we have included all stillbirths and deaths within the first few hours, whether attributable to labour or not.

HOSPITAL PRACTICE

From the records of the Royal Devon and Exeter Hospital one of us (A G) collected 64 cases of breech presentation Of these, 28 occurred among primigravidæ and 19 among multiparæ in the remaining 17 cases no note of parity was made Successful versions were noted in 11 cases and these are not further considered Version was noted as unsuccessful in 9 cases (some of which were subsequently delivered vaginally and some by cæsarean section) Maternal mortality in this series was nil, the infant mortality 10 Cæsarean section was performed in 26 cases of which 14 were primigravidæ and 7 multiparæ, in the remaining 5 no note was made Among these there was only 1 neonatal death a monstrosity with hydrocephalus and spina bifida which survived an hour Among the 27 infants delivered vaginally as breech or footling there were 8 deaths Unfortunately many of the records are incomplete, but the following brief notes are given for what they are worth —

CASE 1 —Multipara Aged 23 Breech Hydramnios Spontaneous delivery of very small baby which survived an hour only

CASE 2 —Primipara Aged 32 Breech with extended legs, three unsuccessful attempts at version Surgical induction No notes of delivery

CASE 3 —Multipara 2 Aged 34 Breech with extended arms and head Alleged contracted pelvis

CASE 4 —Primipara Aged 29 Breech with flexed legs. Failed version. No notes of delivery.

was not always complete in a few cases in which the wounds were examined after 4 or 6 hours

In some cases sulphathiazole was used It was found to be almost completely undissolved after 24 hours, but most of it had disappeared if left for 48 hours It appears to have been less effective than sulphanilamide in these circumstances against *Streptococcus pyogenes*, but has freed a small number of wounds of *Pseudomonas pyocyanea* and *Proteus* Sulphanilamide has not been *successful with the latter organisms*

RESULTS

Group-A infections—In 21 cases with 33 wounds infected with *Streptococcus pyogenes* the local application of sulphanilamide powder resulted in the permanent disappearance of the microbes In 3 cases with 10 sulphanilamide was also given by mouth, and in these the streptococci also disappeared In 4 cases a recrudescence of infection followed grafting operations which were carried out within ten days of obtaining the first negative swab from the wounds concerned Owing to the procedure then followed the wounds were not dressed for several days, and powdering could not be continued The streptococci were of the same type before and after grafting in each case One other case should probably be classed under this heading, but the type of streptococcus originally present is not known The infection reappeared in one case four days after the discontinuance of powdering Another patient who returned to hospital a month after discharge with a small ulcer on a grafted area was also found to be harbouring hæmolytic streptococci in this ulcer In all these cases the infection responded to a further course of treatment, with the exception of the last, who had to leave hospital before treatment could be started, for urgent domestic reasons

Group-C infections—In one case a wound was freed of group-C streptococci and healed uneventfully

Group-G infections—In one case these streptococci disappeared with local treatment only, in another with local and simultaneous oral therapy, and in a third case, unsuitable for local therapy (compound fracture of the mandible), with oral sulphanilamide only

Group-D infections—In 4 cases this streptococcus has been found to resist local treatment with sulphanilamide

ILLUSTRATIVE CASE-RECORDS

The signs + ++ and +++ indicate the presence and abundance of hæmolytic streptococci in culture, the sign − indicates a negative culture, Sm or Stz 1/d indicate the local application of sulphanilamide or sulphathiazole powder respectively once daily

Since no *Strep pyogenes* were found in the throats patient or the nursing staff, and since no other patient same ward was harbouring a streptococcus of identica it is thought that the organism, which was resistant to ment, remained in the depths of the granulation tissue final result, after two failures, is satisfactory

DISCUSSION

In view of the well-recognised tendency for hæm streptococci to persist in open wounds, it seems probable that their prompt disappearance from so wounds in this series after the beginning of local ment with sulphanilamide was in fact due to the and not to coincidence

Dusting with sulphanilamide certainly had no a effect on the healing process, indeed, in the ma healing seemed to be much accelerated when the st cocci disappeared In a few cases the actual are *traced on sterile Cellophane at intervals and* me ments of the area were made by planimeter* such case showed a reduction from 17 6 to 10 7 sq 5 days, and another from 5 2 to 2 0 sq cm in 8 Further observations of this kind are required I confirm the impression of rapid healing we have ob hitherto, the question will arise as to whether the acc tion was entirely attributable to the elimination streptococci, or was perhaps due in part to some stim action of sulphanilamide

The results obtained on superficial wounds with exudate do not justify the assumption that sulp amide introduced into a freely suppurating deep sulphathiazole in 15 cases of staphylococcal septicæmia, only 1 patient dying, no clinical details of any of his cases were given. Butler (1940) reported 5 cases of severe staphylococcal infection treated with sulphathiazole, with 4 deaths McCrea (1940) cured 2 cases of staphylococcal septicæmia with the drug In a previous paper (Melton 1940) I reported 11 cases of staphylococcal infection 2 with positive blood-cultures all of whom recovered

---

* For these measurements we are indebted to Mr C W Bu Basingstoke

In this paper I am reporting the results of sulphathiazole treatment in 30 cases of staphylococcal infection, including the 11 cases already described[*] Most of these infections were of a severe type

ACUTE OSTEOMYELITIS WITH SEPTICÆMIA

There were 5 patients in this group and 2 of them died

CASE 1[*]—Girl aged 11 years Osteomyelitis of ilium Admitted April 4 1940, on 5th day of disease Very ill Blood-culture grew *Staphylococcus aureus* Plaster immobilisation. From 5th to 10th day sulphathiazole 6 g given intravenously plus 38 g by mouth Maximum concentration of free sulphathiazole in blood 3 8 mg per 100 c cm Blood culture remained positive and pyrexia high On 11th day surgical drainage of subperiosteal abscess of ilium On 20th day open drainage of suppurative arthritis of hip Pyrexia still high after operations Later course of sulphathiazole discontinued because of increased pyrexia due to drug fever Staphylococcal antitoxin (20 000 units) and blood-transfusion given on 27th day resulted in temporary improvement On 39th day blood-culture sterile From 40th to 43rd day a total of 48 g of sulphapyridine was given and this was followed by slight reduction of pyrexia but the child was not finally apyrexial until 5 weeks later Radiographs then showed extensive osteomyelitis of ilium Ankylosis of hip on discharge

Here the drug produced no obvious effect but the patient recovered

CASE 2—Girl aged 16 years Osteomyelitis of tibia Admitted June 25 1940 on 3rd day of disease Very ill On 4th day surgical drainage of subperiosteal abscess No improvement Blood-culture taken on 6th day grew *Staph aureus* From 10th to 18th day 8 g of sulphathiazole given intravenously plus 92 g by mouth No effect on blood culture or general condition Between 19th and 21st day staphylococcal antitoxin (100 000 units intravenously and intramuscularly) and blood-transfusion given with temporary improvement On 34th day blood-culture positive On 37th day patient died. Autopsy showed bacterial endocarditis with multiple abscesses

In this case the drug did not affect the disease

CASE 3—Girl, aged 8 years Osteomyelitis of pubic bone Admitted Aug 23, 1940, on 5th day of disease Profoundly toxic with metastatic inflammation in lungs and right radius Blood-culture grew *Staph aureus* Leg immobilised in Thomas splint. Sulphathiazole (65 g) given by continuous intravenous drip for 6 days Maximum concentration of free sulphathiazole[†] in blood 14 7 mg per 100 c cm Striking clinical improvement, with sterile blood-culture and apyrexia, after 5 days On 12th day recrudescence of fever with pericarditis On 18th day surgical drainage of abscess of forearm. On 25th day death from cardiac failure Autopsy showed purulent pericarditis, large deep-seated abscess arising from pubic bone

This patient improved greatly with the drug, her death was probably the result of failure to drain abscesses

CASE 4—Boy, aged 12 years Osteomyelitis of upper humerus Admitted July 20, 1940, on 4th day of disease Very ill Blood-culture grew *Staph aureus* Plaster immobilisation. From 4th to 8th day sulphathiazole, 10 g, given intravenously, plus 32 g by mouth Concentration of free sulphathiazole in blood 5·9 mg per 100 c cm. Definite but temporary clinical improvement with fall in temperature, but blood-culture remained positive (6th day) On 6th and 7th day staphylococcal antitoxin (38,000 units intravenously and intramuscularly) given without definite effect On 8th day drainage of subperiosteal abscess On 13th day blood-culture positive On 15th day drainage of small intramedullary abscess by drilling and saucerisation. From 16th to 19th day a further 36 g of sulphathiazole given by mouth with reduction of pyrexia but patient not finally apyrexial until end of 7th week Blood-culture sterile on 28th day Between 6th and 10th day metastatic foci of inflammation, which subsided without suppuration, in leg foot and arm, as well as dry pleurisy Radiographs after 7 weeks showed extensive osteomyelitis of upper half of humerus with sequestra

Here there was reduction of toxæmia after the drug the patient ultimately recovering

CASE 5—Girl aged 10 months Osteomyelitis of eleventh dorsal vertebra with local abscess confirmed radiologically Admitted Aug 2, 1940, on 14th day of disease On 22nd day surgical drainage of abscess pus showing *Staph aureus* Between 23rd and 26th day sulphathiazole (15 g) given by mouth Improved but pyrexia did not settle completely On 35th day right-sided pneumonia only slightly and temporarily improved by sulphapyridine (12 g) for 3 days Soon became very ill From 40th to 47th day further 4 5 g of sulphathiazole given by continuous intravenous drip followed by 10 g by mouth Rapid improvement with quick fall in high temperature lung condition and sinus of back were clearing up satisfactorily after a few days

This baby showed considerable improvement after the drug Clinically it was a case of septicæmia, although blood-culture was not done

ACUTE OSTEOMYELITIS WITH STERILE BLOOD-CULTURE

In this group 7 cases were treated without a death *Staph aureus* was found in pus from abscesses associated with diseased bone in 6 cases

CASE 6—Osteomyelitis of lower radius and ulna Infection followed open reduction for fracture Exacerbation of fever plus rigor resulted from manipulation of fragments Sulphathiazole (26 g in 4 days) followed by rapid fall in temperature within 36 hours the local infection recovering slowly with sequestrum formation

CASE 7—Osteomyelitis of lower humerus, 5 days illness Sulphathiazole (48 g in 9 days) No fall in temperature Subsequent surgical drainage of subperiosteal abscess followed by rapid apyrexia Radiographs 3 weeks later showed no bone disease

CASE 8—Osteomyelitis of upper humerus 3 weeks pyrexia followed by surgical drainage of intramedullary abscess From day after operation sulphathiazole (80 g) given in a week Apyrexial in a few days

CASE 9—Osteomyelitis of lower femur On 4th day after onset drainage of intramedullary abscess by saucerisation Sulphathiazole begun next day and 74 g given in a week Apyrexial after 4 days

CASE 10—Osteomyelitis of acetabulum with local abscess, following chronic osteomyelitis of tibia with sinus No improvement after sulphathiazole (22 g in 2 days) Rapidly apyrexial after drainage of abscess

CASE 11—Osteomyelitis of upper femur, 2 days' history with severe toxæmia Blood culture grew *Staph albus* (coagulase-negative probably contamination) Immobilised in plaster Sulphathiazole given by mouth (16 g in 2 days) without improvement followed by 6 g intravenously in 24 hours Free sulphathiazole in blood 2 hours after 1 g intravenously 5 7 mg per 100 c cm Rapid fall in temperature Blood-culture while on drug sterile Surgical exploration at beginning of intravenous therapy showed no pus in medulla Radiography after 3 weeks showed no definite bone disease

CASE 12—Osteomyelitis of spine (dorsal 9 and 10) with local abscess Sulphathiazole (105 g in 6 days) given in 6th week after onset, resulted in 4 days apyrexia followed by drug fever and rash. Fever subsided rapidly when drug discontinued Plaster bed when patient already apyrexial

In 5 of these cases the drug was followed by clinical improvement, and in 2 it was without effect

CHRONIC OSTEOMYELITIS

CASE 13—Brodie's abscess lower femur Surgical drainage of abscess After 4 days postoperative pyrexia sulphathiazole (49 g in 4 days) was followed by rapid fall in temperature

CASE 14—Osteomyelitis of lumbar vertebra with continued pyrexia and discharging sinuses 10 weeks after surgical drainage of abscesses over spine Blood-culture sterile At end of this period 96 g of sulphathiazole given in 10 days Permanently apyrexial 10 days after discontinuing drug

---

[*] Cases 1, 6 7 11 13 15 20 21 23 have been described in *Proc. R. Soc Med* 1940, 33 651

[†] Sulphathiazole estimations were carried out by Marshall's method

CASE 5—Primipara Aged 29 Breech with prolapsed cord

CASE 6—Multipara 1 Aged 26 (First baby stillborn, ? cause) Breech with extended legs Admitted to hospital after being in labour 24 hours Legs and arms brought down

CASE 7—Parity unknown Aged 28 Breech with extended legs In labour 12 hours Legs and arms brought down Difficult delivery

CASE 8—Primipara Aged 19 Breech Vaginal delivery No notes of delivery

PRIVATE PRACTICE

From the records of our private practice we (M and L N J) collected 36 cases of breech presentation Of these 24 occurred in primigravidæ and 11 in multiparæ, in the remaining case no note was made None was treated by cæsarean section Version was unsuccessfully attempted in 2 cases Of the remainder, some were emergency calls for help from midwives or neighbouring practitioners, some were missed by one or other of us at antenatal examination so that version was not attempted, and some were deliberately left Maternal mortality in this series was nil, the infant mortality 9 The cases where the baby died were as follows —

CASE 1—Primipara Aged 26 Nurse's call for prolonged labour L S A Slow delivery Delay with after coming head which was finally delivered by forceps Male child weighing 8–9 lb Subsequent successful pregnancy

CASE 2—Primipara Aged 21 Nurse's call Born before arrival of either nurse or doctor Small male child Unmarried mother who concealed her pregnancy Not known if ever subsequently pregnant

CASE 3—Primipara Aged 25 Nurse's call L S A Resistant soft parts, ? contracted pelvis Extended arms and legs brought down Attempt to deliver head by forceps unsuccessful Finally delivered by jaw and shoulder traction and fundal pressure Long labour (40 hours) Not known if ever subsequently pregnant

CASE 4—Primipara Aged 24 Nurse's call R S P Extended arms and legs brought down Delay with head Large male child Probably "helped" too soon Subsequent successful pregnancy

CASE 5—Primipara Aged 36 Called in by another practitioner Protracted labour Legs brought down with difficulty One arm brought down but difficulty with head and extended right arm Fracture of right clavicle Long, thin male child born moribund Breathed 3 or 4 times only Not known if patient subsequently pregnant

CASE 6—Multipara 1 Aged 34 R S P when first seen but rotated to L S A Footling Contracted pelvis (diagonal conjugate 3 in) Delay with head Large female child stillborn Subsequent pregnancy and cæsarean sterilisation

CASE 7—Primipara Aged 24 Called in by another practitioner Contracted pelvis Arms brought down with difficulty Head delivered by jaw and shoulder traction Stillborn *female child* Subsequent *successful pregnancy*

CASE 8—Primipara Aged 22 Called in by another practitioner Shoulder presentation turned to breech Leg brought down Prolapsed cord Arm pushed up and second leg brought down Some delay with head Finally delivered by jaw and shoulder traction Lean male stillborn child Subsequent successful pregnancy.

CASE 9—Multipara 1 Aged 27 Born before doctor's arrival Nurse failed to deliver head Large female child stillborn

COMMENTARY

It would be idle to attempt to draw conclusions from a mere 100 cases, but certain points of interest emerge First, it may be noted that among these quite unselected cases there was no maternal mortality Secondly, cæsarean section undoubtedly gave the best immediate results, in 26 cases so treated there was only one fœtal death and that, a monstrosity, was a merciful release There can be no question that this simple and dramatic operation, attended with little immediate risk to mother or child, is a valuable weapon in the treatment of breech presentation, it is always at hand in hospital practice though less accessible to general practitioners, especially in country districts The third point is that breech delivery per vaginam greatly increases the risk to the child, the figures were In hospital, 27 cases, 8 infant deaths (30%), in private, 36 cases, 9 infant deaths (25%) So far as can be judged from the case-records there is no reason to suppose that the difficulties attending delivery differed appreciably in the two series. Altogether, of 63 children born vaginally breech first, 18 died

Breech delivery, then, is a hazardous proceeding, and it should be less common than it is Careful antenatal examination, supplemented where necessary by radiology, should reveal the presence of breech presentation, so that version can be attempted If version fail, cæsarean section becomes the treatment of choice especially in primiparæ or in cases where some degree of pelvic contraction is diagnosed It may be noted, however, that the risk of stillbirth is probably comparatively slight when vaginal delivery is carried out on a multipara with a good obstetric history by a skilled and patient accoucheur

It would be interesting to know to what extent, if any, cæsarean section or difficult vaginal delivery (with a fair risk of a stillborn child at the end of it) acts as a psychological deterrent to further pregnancy We are not, of course, in a position to answer this question, but at least 2 of our patients treated by cæsarean section had previously been delivered by this method, 1 of them twice Of the 36 women delivered vaginally in private practice 10 have had subsequent successful pregnancies, 15 have not risked it again, and of 11 we have no record Of the 9 mothers of stillborns, 6 have since had one or more children, 1 has not yet become pregnant again so far as we know and 2 are untraced This suggests that stillbirth is not a deterrent but rather a stimulus to try again, whereas difficult labour resulting in a live child may tend to persuade the mother to rest on her laurels

SUMMARY AND CONCLUSIONS

Of 100 consecutive cases of breech presentation in hospital and private practice, 11 were treated successfully by version and delivered as vertices, 26 were delivered by cæsarean section and 63 by the vagina

There was no maternal mortality but the total of stillbirths and neonatal deaths was 19, only 1 being among the infants delivered by cæsarean section

With increasing antenatal care breech delivery should be less common than it is If breech presentation is diagnosed version should be attempted If version fails cæsarean section is the treatment of choice, especially in primiparæ or where some degree of pelvic contraction is diagnosed

Breech vaginal delivery is less risky to the child in multiparæ than in primiparæ

Breech presentation with the baby born dead is not apparently a deterrent, either psychological or physical, to future successful pregnancy

---

SULPHATHIAZOLE IN TREATMENT OF STAPHYLOCOCCAL INFECTIONS

By GEORGE MELTON, M D Lond, M R C P
SENIOR RESIDENT PHYSICIAN AT LEWISHAM HOSPITAL LONDON
COUNTY COUNCIL

THERE is ample experimental evidence of the effective bacteriostatic action of sulphathiazole and sulphamethylthiazole on staphylococci (Barlow and Homburger 1939, Herrel and Brown 1939, Long 1940, Macdonald 1940 Fleming 1940), but clinical data have consisted mainly of reports demonstrating their value in urinary infections (e g Pool and Cook 1940) Records of their action in the more severe types of staphylococcal infection, particularly in those associated with septicæmia, have mo th been confined to very small groups of cases

Herrel and Brown, employing sulphamethylthiazole, obtained a cure in a case of staphylococcal septicæmia and a favourable response in 2 cases of staphylococcal cellulitis Keliher (1940), using the same drug, cured a patient with staphylococcal septicæmia Gsell (1940) reported 2 cases of staphylococcal septicæmia unsuccessfully treated with sulphathiazole Paterson *and* Walker (1940) were able *to* cure a baby with staphylococcal septicæmia with the same drug Dietel (1940) succeeded in curing a baby with staphylococcal meningitis Carrol (1940) and Stirling (1940) each reported cures in 2 cases of staphylococcal septicæmia Spink (1940) in an interim report referred to satisfactory results with

The dosage employed varied considerably At first it was the practice to administer 1 g intravenously for three to six doses, followed by 1–2 g by mouth 4-hourly Subsequently for severe cases in adults the dose was increased to 3–4 g 4-hourly In septicæmia it has latterly been my custom to give the drug by continuous intravenous drip the daily dose being 20–25 g for adults, 10–12 g for children and 3 g for infants The sodium salt was dissolved in half-strength normal saline made isotonic with glucose and the drip feed regulated so that enough solution was run in to raise the sulphathiazole concentration in the blood to 15 mg per 100 c cm In practice this has been difficult to achieve The duration of sulphathiazole treatment has varied from 2 to 16 days most of the courses lasting from 5 to 7 days The difficulty of maintaining a sufficiently high concentration of the drug in the blood is due to its rapid excretion When the drug is given by mouth it is rapidly absorbed Reinhold (1940) noticed that after a single dose of 3 g , the highest blood-concentration in the majority of cases was reached after 2 hours and that after 4–6 hours the level was still above 4 mg per 100 c cm With continued oral administration of 1 g 4-hourly, concentrations of free sulphathiazole in the blood ranged from 1 2 to 19 mg per 100 c cm , averaging 5 45 mg Comparable figures were obtained by Gaisford and Whitelaw (1940) In the present series, free sulphathiazole varied from 1 6 to 8 7 mg per 100 c cm (average 4 6 mg) after 1 g 4-hourly, from 2 2 to 13 2 mg per 100 c cm (average 6 mg) after 2 g doses and from 3 to 9 6 mg per 100 c cm (average 6 5 mg) after 3 g doses

Long (1940) comments on the fact that after the first 24 hours of treatment concentrations of sulphathiazole in the blood are often much lower than would be expected from experience with similar doses of sulphapyridine, and that it is sometimes difficult to maintain an adequate concentration despite increases in dosage The necessity for giving copious fluids to prevent deposition of crystals of sulphathiazole in the renal tubules may help to lower the blood-concentration by promoting excretion In the elderly patients in whom renal function was impaired high blood levels were more readily reached—e g case 23 with 13 2 mg per 100 c cm on 2 g doses This fact has been observed in connexion with the other sulphonamides Since some degree of renal impairment is present in many old people their dosage should be adjusted by estimations of the levels in the blood It is worthy of note that, in the septicæmic group, blood-cultures became sterile in cases 3 and 23 with concentrations of 13–15 mg per 100 c cm but remained positive in cases 1 and 4 with concentration of 5–6 mg , despite the fact that the former two patients were more seriously ill

Sulphathiazole is reported to be less likely to cause vomiting than sulphapyridine and our experience supports this Vomiting severe enough to interfere with the administration of the drug occurred in only 1 patient 4 patients vomited occasionally after the tablets , and 2 vomited after intravenous administration, one of these also developing a transient urticarial eruption after each injection Drug rashes of the characteristic " erythema-nodosum " type were seen in 5 cases, usually associated with drug fever One of the patients developed severe conjunctival congestion with irritation of the eyes , similar symptoms were noted by Long in some of his cases

No evidence of renal damage other than transient albuminuria was observed, and even this could not always be attributed to the drug Case 23 with a high blood-urea before treatment was not adversely affected by sulphathiazole and the blood-urea became normal In case 25 the blood-urea did rise from 34 to 56 mg per 100 c cm while the drug was being taken, but quickly returned to normal when it was stopped Long found it necessary in some of his cases to discontinue the drug for hæmaturia‡ and anuria, but neither appeared in this series Daily measurement and testing of the urine are important, however

Moderate leucopenia below 6000 cells was seen in 10 cases, the lowest count being 4500 in 2 cases The count soon became normal again when the drug was discontinued In case 3 the count rose from 5500 to 11,500 while the patient was on sulphathiazole, and this rise corresponded to considerable clinical improvement When leucopenia develops it is necessary to consider stopping the drug , in very ill patients it would be inadvisable to do so unless the leucopenia became pronounced

CONCLUSIONS

The evidence goes to show that sulphathiazole is a therapeutic agent of value in staphylococcal infections Its action in staphylococcal septicæmia however has so far proved to be limited Early diagnosis is clearly essential to successful therapy with sulphathiazole, for failure and death occurred only in the advanced cases Fleming (1940) has shown that the action of the sulphonamides on suppurative inflammatory foci is inhibited by the presence of peptones in the pus Thus abscesses —whether local or metastatic—will prevent successful therapy unless they are accessible to surgical drainage Possibly large doses of sulphathiazole (controlled by repeated blood estimations) will give more satisfactory results in septicæmia particularly in the early stages of acute osteomyelitis before suppuration has taken place Fleming has also shown that the growth of staphylococci can be inhibited by a dilution of 1 in 60 000 sulphathiazole Such a level would probably be inadequate in the severe human infections and the findings in this series support the view that a blood concentration of 15 mg per 100 c cm is necessary for therapeutic success Staphylococcal antitoxin may enhance the action of the drug in the septicæmic cases

The best results were obtained in the milder cases, and although many of these would have recovered without sulphathiazole there is no doubt that in some of them it reduced toxæmia and hastened recovery As Butler has noted, sulphathiazole helps to reduce the toxæmia and fever which may persist after surgical drainage of abscesses or removal of the foci of infection

Sulphathiazole is less toxic than sulphapyridine in similar doses and experimentally has been found to be more potent against staphylococci , but it is more difficult to maintain high blood-concentrations of sulphathiazole than of sulphapyridine The decision on which is the more effective clinically must await further research

SUMMARY

A series of 50 cases of staphylococcal infection, mostly of severe type have been treated with sulphathiazole

In staphylococcal septicæmia the drug was of value when given early and in adequate doses, and rapid improvement which could be attributed to the drug occurred in 5 out of 13 cases In acute osteomyelitis it did not lessen the need for surgical drainage or check the progress of suppuration, but it helped to reduce toxæmia Many of the carbuncles ceased to extend when the drug was begun and the pyrexial period appeared to be shortened, but there were 2 deaths out of 5 cases of carbuncle on the upper lip or nose both in patients with cavernous-sinus thrombosis present before treatment was begun The drug was also found of value after surgical drainage had been instituted, in clearing up the toxæmia and accelerating the subsidence of the local lesion

It was found difficult to maintain an adequate concentration of sulphathiazole in the blood except in elderly patients because of rapid excretion, and in septicæmic cases the drug is best given as the sodium salt in isotonic solution by intravenous drip A concentration of 15 mg per 100 c cm in the blood should be attained

Vomiting is less common than with sulphapyridine, and the only other toxic effects seen were skin eruptions, conjunctival congestion and moderate leucopenia

I wish to thank Dr W Allen Daley, medical officer of health for the London County Council, for permission to treat the above cases, and the medical superintendents of the various L C C hospitals at which this research was carried out The sulphathiazole used in the clinical trials was supplied by Pharmaceutical Specialties (May and Baker) Ltd

‡ One of my ex patients (not in this series) developed hæmaturia with extreme oliguria this subsided when the drug was discontinued and 10% glucose saline was given intravenously

CASE 15 —Osteomyelitis of upper femur Surgical drainage of subperiosteal and metastatic abscesses of thigh followed by many weeks pyrexia and pathological fracture of femur Sulphathiazole begun on day after immobilising fracture in Thomas splint and 40 g given in 5 days Became apyrexial for 10 days (first time for many weeks) Relapsed subsequently

CASE 16 —Osteomyelitis of cuboid with discharging sinuses and mild pyrexia, not affected by sulphathiazole (46 g in 1 week)

CASE 17 —Osteomyelitis of tibia with sinuses Sulphathiazole (45 g in 3 days) given after failure of sulphapyridine to reduce fever Followed by increase in pyrexia and congestion of sclera (toxic manifestations of sulphathiazole) On discontinuing drug became rapidly apyrexial

There was definite improvement in 3 cases out of 5 in this group

CARBUNCLES

Of 22 cases of carbuncle treated with sulphathiazole *Staph aureus* was grown on blood-culture in 5 Magnesium or sodium sulphate was applied locally in all cases The results, with some illustrative cases, are as follows —

There were 5 cases of carbuncle in the danger zone—the upper lip and nose, with 2 deaths, both in patients who were moribund before treatment began

CASES 18 and 19 both had positive blood culture (*Staph aureus*) and both died with cavernous sinus thrombosis, present before therapy began

CASES 20 and 21 —In both of these the carbuncles subsided without sloughing, case 20 being apyrexial in 5 days and case 21 in 3 days

Of 4 cases of carbuncle on the lower lip, 1 had a positive blood-culture but all recovered

CASE 23 —Aged 71 with septicæmia Blood culture grew *Staph pyogenes* Blood-urea 96 mg per 100 c cm Sulphathiazole (3 g intravenously plus 80 g by mouth) given in 13 days, became apyrexial after 48 hours with sterile blood-culture after 11 days Maximum concentration of free sulphathiazole in blood 13 2 mg per 100 c cm Developed small empyema with *Staph pyogenes* in pus, which cleared up after single aspiration Blood urea normal on discharge

Of 13 cases of carbuncle on the scalp, neck or back, 3 had positive blood-cultures and there was 1 death

CASE 24 —Carbuncle of back and septicæmia Pneumonia and heart failure Blood culture grew *Staph aureus* Sulphathiazole given (12 g intravenously and 86 g orally in 7 days), temporary fall of temperature Staphylococcal antitoxin (42,000 units intravenously and intramuscularly over 4 days) produced further improvement Not apyrexial until 5 weeks, blood culture then sterile Sterile pleural effusion aspirated once

CASE 25 —Aged 79, with carbuncle of neck Blood culture grew *Staph aureus* Sulphathiazole (102 g by mouth in a week) Apyrexial after 4 days Sterile blood culture after 6 days

CASE 26, aged 79, with carbuncle of scalp and multiple subcutaneous abscesses, moribund before treatment began and died after 16 hours Of 4 carbuncles in diabetics all recovered satisfactorily

MISCELLANEOUS CASES

A group of 11 cases, 2 with positive blood-cultures

CASE 40 —Staphylococcal pyæmia resulting from cervical abscess after an insect bite Blood cultures grew *Staph aureus* throughout treatment Local cellulitis improved after incision and drainage Soon very ill with pneumonia and meningitic symptoms Failure with sulphapyridine (24 g), sulphathiazole (12 g intravenously plus 66 g by mouth in 6 days) together with staphylococcal antitoxin (120,000 units intravenously and intramuscularly over 4 days) Free sulphathiazole in blood (3 hours after 2 g) was 2 9 mg per 100 c cm Did not improve and died a week later Autopsy bacterial endocarditis with multiple pyæmic abscesses

CASE 41 —Staphylococcal pyæmia and suppurative arthritis of knee following infected graze Blood cultures grew *Staph aureus* throughout treatment Pneumonia and multiple subcutaneous abscesses Sulphapyridine (28 g in 3 days) given without effect From 11th to 13th day of disease 50 g of sulphathiazole given by continuous intravenous drip, but patient died after 4 days Free sulphathiazole in blood 11 2 mg per 100 c cm

Both these cases had advanced septicæmia with pyæmic abscesses before sulphathiazole therapy was begun

CASE 42 —Perinephric abscess following furunculosis Sterile blood culture Pyrexia for a month in hospital Sulphathiazole (6 g intravenously plus 54 g by mouth in 5 days), followed by striking improvement, patient becoming permanently apyrexial and mass disappearing from loin in a few days

CASE 43 —Staphylococcal pelvic abscess and cellulitis following septic abortion Blood-culture negative Very ill, pyrexia for a month before abscess began to discharge per vaginam Discharge ceased after 2 days, but pyrexia remained high and pelvic mass large Sulphathiazole then given (2 g intravenously plus 42 g by mouth in 4 days), striking improvement Permanent apyrexia after 6 days when mass was subsiding satisfactorily

CASE 44 —Large alveolar abscess pointing in submaxillary region was incised, but ceased to drain and pyrexia remained high After sulphathiazole (18 g by continuous intravenous drip plus 24 g by mouth in 3 days) temperature fell rapidly in 12 hours and swelling subsided, with slight discharge only, in 48 hours Blood culture sterile Pus contained *Staph aureus*

CASE 45 —Breast abscess rapidly subsided after single aspiration, sulphathiazole (36 g in 3 days) being given immediately after aspiration Pus contained *Staph aureus*

CASE 46 —Whitlow of finger following abrasion Pus contained *Staph aureus* Sulphathiazole given (36 g in 3 days), Whitlow incised next day, no pus found Inflammation subsided after a few days

CASE 47 —Baby aged 3 weeks with pneumonia, staphylococcal abscesses of thigh and wrist, both incised Sulphathiazole (3 g by mouth followed by 3 g intravenously in 2 days) was without effect and the baby died after 2 days

CASE 48 —Staphylococcal peritonitis in baby 8 days old, was operated on and then given sulphathiazole (3 g in 3 days) No improvement, death

CASE 49 —Staphylococcal pyopneumothorax complicating phthisis Sulphathiazole given before drainage without benefit

CASE 50 —Alveolar abscess of cheek Unaffected by sulphathiazole, but cleared up rapidly after drainage

DISCUSSION

In this series 11 patients had positive blood-cultures, present on more than one occasion in all of them, no blood-cultures were done on cases 5 and 47 although clinically they had septicæmia Of these 13 patients, 7 died In only 1 of the fatal cases (case 3) and 2 of the non-fatal cases (23 and 25) was the blood-culture made sterile during treatment with sulphathiazole Antitoxin was given simultaneously with sulphathiazole in 1 case, and after a course of the drug in 3 others, without apparent effect In only 1 case (24) was antitoxin successful after sulphathiazole had produced only temporary improvement

In 8 cases of osteomyelitis, pyrexia was reduced while sulphathiazole was being given, but surgical drainage had already been carried out in 6 of them Cases 7 and 10, which showed no improvement on the drug, rapidly responded when surgically drained In cases 16 and 17, which had already been operated on before sulphathiazole administration, the pyrexia did not settle when the drug was given, indeed, in case 17 drug fever developed rapidly

All cases of carbuncle with sterile blood-culture, except case 25, cleared up satisfactorily, the pyrexial period varying between 3 and 7 days from the time of starting the drug

In the miscellaneous group 5 cases cleared up rapidly as soon as sulphathiazole was started Probably in all of them the actual amount of suppuration was small, the condition present being mainly cellulitis The 2 cases in which the drug was tried initially without effect responded readily to surgical drainage

In many cases the drug appeared to have no dramatic effect on the local disease In osteomyelitis the condition progressed to suppuration, and in cases 1 and 4 extensive areas of bone were involved and sequestra were seen radiographically Cases 7 and 11 appeared to make a complete recovery without radiological evidence of bone disease, but in these the focus in the bone may have been small Most carbuncles appear to have run the usual course, though they did not extend, as a rule, once the patient had begun taking the drug, and 2 of the facial ones subsided without obvious sloughs to the depths of the exuberant spongy granulation tissue Efforts were therefore made to reduce the tissue to a flat area, less inviting to bacterial growth, by pressure bandages of tulle gras over which saline was applied Ten-minute dressings of eusol or spirit were sometimes applied for two hours, and ultra-violet light through paraffin was tried In those days only 10% of the grafts took properly and the percentage of failures was in the forties The introduction of the sulphonamides altered everything Now ordinary agents are used to get rid of sloughs and produce "social cleanliness" in the wound if sulphonamide is used from the first the sloughs may take longer to separate Then sulphonamide powder is gently massaged into the granulations with a spatula which seems to be a little more efficient than insufflation and a dressing of tulle gras and saline is applied The powder is put on daily Before, at and after operation the drugs are given by mouth The granulations are excised and the powder massaged into the serum in the wound Over the whole of this area the skin graft is applied, and pressure dressings put on and left for seven days The number of cases is now over 40 and (apart from the one failure who received no sulphanilamide by mouth) there has been no cellulitis or infection and at least 75% of the grafts have taken The sulphanilamide beneath the graft does not prejudice the take, even though it may be ½ in thick The blood sulphonamide rises to about 3 or 4 mg per c cm and there has been no intoxication All this is extremely encouraging in enabling the surgeon to apply the finest of all dressings—the patient's own skin—before fibrosis and contractures appear

Dr **Frank Hawking** drew attention to the possible use of sulphonamide compounds in preventing gas gangrene Experimental wounds were made in guineapigs and infected with 10,000 lethal doses of *Cl welchii* or *Cl septique* Insertion of sulphonamide compounds at the same time as the infection saved up to 75% of the animals Sulphathiazole was the most effective compound, sulphapyridine was moderately effective, sulphanilamide was good against *Cl welchii* but had no action against *Cl septique* Since sulphathiazole is expensive, a mixture of equal parts of sulphanilamide and sulphathiazole can be used, in experimental wounds this was almost effective as pure sulphathiazole None of the compounds had much action against *Cl œdematiens* In clinical practice, the sulphonamide compound should be reinforced by the prophylactic injection of antitoxin When treatment was delayed for 2 hours the results were much less good, when it was delayed 6 hours all the animals died Therefore treatment should be applied as early as possible Oral treatment was less efficacious than local treatment A number of casualties have now been treated with sulphanilamide or sulphathiazole and have done very well The blood concentration is always low, usually less than 1 mg per 100 c cm In the guineapig wounds sulphanilamide produces a high concentration (about 1000 mg per 100 c cm) but it is all gone within 24 hours, sulphapyridine persists for 7–10 days but the concentration is only 40 mg per 100 c cm, sulphathiazole persists for 4–5 days and the concentration is about 100 mg per 100 c cm Sulphanilamide travels quickly from one end of a wound to the other sulphathiazole fairly quickly, but sulphapyridine travels slowly, and the concentration at the far end is never high. Experiments were made on the diffusion of these compounds through the abdominal wall of the rat from within outwards the wall being 2–3 mm thick. If the tissue is dead sulphanilamide passes through fairly well and produces a fairly high concentration (26 mg per 100 c cm) on the outside but it requires 24 hours to do so, if the tissue is alive, however, with an active circulation the concentration on the outside is never greater than in the body as a whole Thus, if a sulphonamide compound is placed in the cavity of a wound, it will pass down into the crevices, and it will slowly diffuse into pieces of dead tissue But the concentration which it produces in adjacent living tissue will be no higher than that in the body as a whole In order to reach this living tissue the local application should be supplemented by oral administration Finally Dr Hawking referred to previous statements that pus would inhibit the bacteriostatic action exerted by sulphanilamide on bacteria in vitro He treated several wounds containing thick pus by the insertion of sulphathiazole and found that the pus became sterile

Dr **C A Green** said that there were few reports on the effect of body reactions on therapy He described work with *Streptococcus hæmolyticus* in rabbits and Prontosil Soluble In the first experiment the effect of therapy on the response to streptolysin O in the form of culture filtrates was studied in two rabbits There was no indication that prontosil had any effect In a second experiment the effect of prontosil therapy on the antistreptolysin O response in experimental infection by hæmolytic streptococci was studied in four rabbits Despite prontosil therapy the usual reduction in the latent interval before the appearance of the response was noted, and a higher titre was reached than in the original course This combined result was considered definite evidence of the absence of any interference with production of antistreptolysin O as a consequence of the exhibition of prontosil The results indicated little of any interference with production of antistreptolysin O in experimental animals as a result of the simultaneous injection of prontosil These observations might throw some light on the disappointing results of prontosil in the treatment of acute rheumatism

Major **A E Francis** described the results of local sulphanilamide treatment in forty-seven patients with 77 wounds infected with hæmolytic streptococci In twenty cases with 31 wounds infected with group-A hæmolytic streptococci the organisms disappeared entirely with local therapy only A further three cases with 8 wounds received oral as well as local treatment one case (compound fracture of the mandible) received oral treatment only In eleven other cases, with originally 22 infected wounds, 15 wounds became reinfected or resisted treatment Of these two cases had streptococci which were resistant to sulphanilamide in vitro, four cases became reinfected while on leave, one case was found to have an undrained pocket of pus, while in three cases the streptococci reappeared after operations Two cases with group-C streptococci had responded satisfactorily but five cases infected with group D had all resisted treatment, three of them actually developing the infection while under sulphanilamide therapy Three group-G infections had responded well Much exudate prevented the action of sulphanilamide The intelligent coöperation of the staff was essential The drug must not be applied over a dried film of exudate without being moistened with saline Sometimes eusol had been put on top of sulphanilamide, the resulting compound was inactive Bacteria sometimes could be recovered from the surrounding skin after they had disappeared from the wound The skin should therefore be treated with an antiseptic, such as Dettol cream The skin sometimes became rather macerated from the saline packs, but recovered if these were left off for a day

Dr **K Wallersteiner** pointed out the difficulties in estimating the efficiency of these drugs, and described the tests in use with the new Bayer compounds now becoming available One new compound with two sulphanilamide radicles had proved to have great affinity for fibroblasts and to be very efficient A derivative of trypan blue with two sulphanilamide groups had been developed for external application

---

IN their fourteenth annual report the Universities Federation for Animal Welfare (UFAW) admit that they are carrying on under difficulties Their main stronghold, the University of London has been scattered through the provinces, their honorary officers are preoccupied with service duties Since the report was written their London offices have been wrecked by enemy action But UFAW's morale is unshaken Though the war may have restricted their opportunities, under their new president, Sir Peter Chalmers Mitchell, F R S, they are resolute that they will lose no chance of advancing a step here and a step there The scientific investigations committee has been active and new members have been gained, especially in the University of Oxford For the present the work is being carried on from the home of the general secretary and all letters should be addressed to Hall Place, Lyndhurst Terrace, London, N W 3

Medical Societies

ROYAL SOCIETY OF MEDICINE

AT a meeting of the Section of Therapeutics and Pharmacology on Feb 11, with Sir WILLIAM WILLCOX, the president in the chair, a discussion on

Chemotherapy and Wound Infection

was opened by Colonel LEONARD COLEBROOK He said that the struggle against bacterial infection during the last fifty years had taken three roads active and passive immunisation, including surgical drainage, internal antisepsis, and external antiseptics The first reports on red prontosil did not suggest that it would be of great value as an external antiseptic, but later developments showed that it was reduced in the body to sulphanilamide, which had a considerable effect on bacteria It is extremely diffusible, getting quickly into all the tissues, the cerebrospinal fluid and the vitreous and aqueous humours It has a very low affinity for the tissues and serum proteins, and so does not lose potency as the older antiseptics do, 90% or more is excreted in the urine It is innocuous for fibroblasts and leucocytes in high concentration, and is readily absorbed from wounds All these properties, with its powerful action on the streptococcus, make it probable that this drug has real value as an external antiseptic, but this cannot yet be regarded as quite certain Every wound produced by violence is really a honeycomb of spaces filled with serous fluid which is a good culture medium for certain pathogens—called "serophytes" by Sir Almroth Wright The surgeon cannot obliterate all these dead spaces, and until recently the medium in them could not be rendered uncongenial to organisms Solid sulphanilamide introduced into the wound will produce a nearly saturated solution for some hours, up to a strength of 1 400 it does not harm leucocytes, though it may prove to do so in higher concentrations Hæmolytic streptococci will be killed completely by it, without leucocytic action Tests of its action on staphylococci and gas-gangrene bacilli are still wanting Aerial bombardment makes it necessary in this war to have a "pansement d'attente," to hold up sepsis until the surgeon can get to work Experiments have shown that the sulphanilamide group offer much hope in this direction, by applying them early the surgeon can hope to prevent many cases of gas gangrene, to prolong the safe period for débridement, to make delayed primary suture possible on many less severe wounds, to reduce the sepsis rate in compound fractures, to get healing in plaster without suppuration, and to do much better with burns Almost all severe, deep burns now go septic, and so do many of the less extensive ones The best hope of avoiding infection lies in learning how to use one of the sulphanilamide group or one of the newer mysterious related substances Some pastes are now ready for clinical trial in burns For deep burns an occlusive dressing to avert loss of plasma protein may be indicated For streptococcal infections of the skin, sulphanilamide has been used locally and internally with good effect, but it has not been much used as a superficial application only Recent tests suggest that it will be successful in this way This kind of treatment will doubtless lend itself to much abuse, and workers must be careful to check their clinical impressions by all available means

Mr EMLYN LEWIS described methods of treatment in wounds and burns, unfortunately in most wound cases the drug had also been given by the mouth to get the maximum effect The powder is worked over the wound with the finger, he said, to cover the surface, without regard to the recommended dose of 15 g The wound is then sutured, or packed with plain or Vaseline gauze Dressings do not need inspection until the fifth day or later *Wounds usually look impressively healthy*, even if the discharge contains organisms they do not seem to affect the course of the case Sometimes at this stage the wound is obliterated in its depth by catgut stitches and the powder reapplied Two cases of gas gangrene were given M & B 693 by mouth and Streptocide locally, and recovered, although they had not had ideal initial surgical treatment A third case, a through and through wound of the left thigh, was found to have much debris in the tissues and gas gangrene at operation twelve hours later After wide excision and irrigation with peroxide, streptocide powder was applied liberally and M & B 693 given by the mouth The wound healed cleanly Streptocide powder had been used locally for burns of the second and third degree, especially on the face, hands and forearms It was covered with Tulle Gras Results were most encouraging, one girl was able to discontinue dressings on the third day, another on the twelfth day In one case only were toxic symptoms seen after external application

Prof ALEXANDER FLEMING described experiments on the relative potency of variants of sulphanilamide Sulphanilamide itself is not, he said, strong enough to deal with pneumococci or staphylococci, sulphapyridine is stronger and can cope with pneumococci, and sulphathiazole is stronger still and so is effective with staphylococci It is a question of strength rather than of specificity One important point is to test the concentration of the drug in the blood periodically, this is too often forgotten What matters is not the amount of drug given but the amount absorbed No drug which destroys leucocytes more readily than bacteria is useful, no pre-sulphanilamide drug passes this test There are certain limitations in local sulphanilamide therapy Many bacteria and bacterial extracts, some peptones and some chemicals inhibit the action of sulphanilamides, pus fluid may have this effect, so if there is much pus in the wound these drugs may be useless Penicillin, made by the mould penicillium, may surpass the sulphanilamides It is troublesome to make and does not keep very well, and so was not used in peace time Recently, workers in Oxford have isolated a solid impure penicillin which has a remarkable effect on infections both clinically and in the laboratory Weight for weight it is four times as potent as sulphathiazole and so about a hundred times as potent as sulphanilamide The active principle, if it could be isolated, would be more potent still It is not inhibited by the factors which inhibit the sulphanilamides Similar substances have been made from other moulds and organisms and all act in enormous dilutions The action of these drugs seems to be bacteriostatic rather than bactericidal—stopping the growth of the bacteria so that the body cells and fluids will kill them The addition of vaccine treatment to M & B 693 might turn the scale between life and death A small dose of vaccine or the injection of hypertonic salt might be tried in those cases where streptococci do not disappear as they should The combination of immunotherapy and chemotherapy is a good one

Mr RAINSFORD MOWLEM *read a* paper on *sulphanil*amide in skin grafting which he described as a series of impressions He had tried to subject his practice to as severe a test as possible and so far had had only one apparent failure Most of his patients were bombed civilians with multiple injuries needing skin grafts—burns and extensive lacerations They are, he said, usually heavily infected on admission to the unit, though often there are no clinical manifestations of the infection, it nevertheless prevents surgical intervention and causes a high percentage of infected fingers among the nurses In the past the effort to get a clean granulated area for grafting depended mainly on the bacteriostatic powers of the body No antiseptic could be expected to penetrate

The Lister Institute
OF PREVENTIVE MEDICINE.

Therapeutic Substances Act Licence No 9

Anti-Meningococcus Serum
(Globulin Solution)

The results of animal experiments carried out both in this country and in the United States of America have proved that meningococcal infections are best treated by a combination of sulphonamide and serum therapy A combined form of treatment is therefore advised for the treatment of cerebrospinal meningitis in man Both therapeutic agents should be administered at the earliest possible moment The serum may be given intravenously or intrathecally

The serum prepared at the Lister Institute is subjected to a process of purification and concentration whereby a large proportion of the inactive serum protein is removed, the dose of antibody is thus contained in a smaller volume of fluid Uniformity of potency is secured by assaying each batch of serum by a mouse protection test

Three preparations are issued in concentrated form.
(1) Anti-meningococcus serum (multivalent)
(2) Anti-meningococcus serum (Group I)
(3) Anti-meningococcus serum (Group II)

An Anti-Meningococcus Serum for diagnostic purposes is also available

Stocks of the Lister Institute products are maintained at Messrs Allen & Hanburys Ltd Vere Street London W 1 (Telephone Mayfair 2216) and supplies can be obtained at any hour of the day or night

Particulars with regard to these sera are obtainable from

The Factors of the Mind

An Introduction to Factor analysis in Psychology By Cyril Burt, M A, D Sc Oxfd, professor of psychology in the University of London London University of London Press Pp 509 21*s*

The factors of the mind, in Professor Burt's sense of the word, are qualities the existence of which can be deduced from the results of different tests applied to suitable groups of subjects Thus Spearman's *g* is a general factor present in all intellectual processes, as distinct from specific factors, like verbal or arithmetical ability, which occur only within a limited range of processes Factor analysis is the technique by which logical and mathematical principles are applied to the figures obtained from psychological tests first used on empirical grounds and presumed to measure some factors of the mind The possibility of measuring these factors is still criticised, and Professor Burt is at pains to defend it He notes that the relative order of merit of pupils, as judged by class-teachers, may prove incapable of useful analysis because " merit " denotes a complex and therefore doubtful quality , but it may be analysable into two or more factors, such as intelligence and industry and perhaps speed of memorisation, that are independent of each other and can usefully be arranged in a linear series He claims, in face of opposition both ancient and modern, that his material is fit subject matter for science because its agreement with facts is demonstrated by the power of prediction , for, says he, " the psychologist's prediction of what a child will do in certain tests tomorrow is far more accurate than the meteorologist's predictions of what tomorrow's weather will be " Practice and theory are closely linked in the book, a pretty problem being given by that common experiment in which a group of persons is asked to rank a series of English compositions in order of merit If the group are school-children, and the compositions are by authors of known repute, then we incline to treat the results as a measure of the children's powers of appreciation , but if the compositions are children's essays then grown-up judges in their pride treat the results as a measure of the value of the essays The factorial analyst would say that the results express the interaction between the test stimuli and the qualities of the judges , which of these we treat as constants and which as variables depends upon what we are trying to study and how we plan the experiment

This book deals with only a part of a subject in which Professor Burt is an acknowledged master It must be confessed that the mathematical descriptions and discussions are not easily within the scope of many of us, but now that the connexion between emotional make-up and physical disorders is becoming recognised and clinically studied we must keep a watchful eye on such work as this Those concerned, for example, in working out statistically the relation between temperamental qualities and the incidence of peptic ulcer might find help and confirmation in the use of factor-analysis, for Professor Burt indicates that his theorems are applicable to the factorisation not only of intellectual but of emotional, moral, or temperamental traits

The Foot and Ankle

By Philip Lewin, M D , F A C S , associate professor of bone and joint surgery, Northwestern University medical school , professor of orthopædic surgery, post graduate medical school of Cook County Hospital London Henry *Kimpton* Pp 620 *42s*

Dr Lewin has written a book on the foot and ankle for " the student, general practitioner, industrial surgeon and the younger orthopædic surgeon " , a truly formidable task In the opening chapters he gives an excellent account of the practical anatomy and the physiology and mechanics of the normal foot and ankle, after which he discusses the abnormalities which may occur These chapters are followed by a detailed description of that often neglected article, the shoe, and clear diagrams are given to show modifications of the ordinary commercial shoe for the relief of various orthopædic conditions In succeeding chapters most of the known disorders o foot and ankle are discussed, but Dr Lewin would been more helpful if he had given more details of acc methods of treatment Thus in the chapter on pl technique Bohler's non-padded plaster is dismisse three lines, and fractures and dislocations are also with somewhat briefly, though they are well illust by line drawings No details are given of the co application of plaster-of-paris, which is so ess to the maintenance of reduction and the avoidan many complications, and in a short section on mi orthopædics no mention is made of the use of the sul amide drugs in the treatment of infected wounds is the application to military surgery of the wo Winnett Orr and Trueta referred to Poliomyel well described, a detailed account being given o symptoms, differential diagnosis and treatment, the section on the treatment of the residual par is overloaded , the author refers to at least eight of arthrodesis of the tarsal joints Circulatory turbances of the leg are described in considerable and will help those called on to treat such cond A well-illustrated section on surgical technique is incl The appendix of pedigrams contains several wisec This work sets out to help too many classes of m men and so does not quite take its due place as a book , but if it acts only as a guide to papers and ar and as an outline of many operations and other me of treatment, it will serve a good purpose

Fractures and other Bone and Joint Injuries

(2nd ed) By R Watson Jones, M Ch (Orth) F R C S Edinburgh E and S Livingstone P *50s*

This work is well arranged, fully and aptly illust and written in an epigrammatic style which does than clothe the bones For the postgraduate it m called an essential book, providing as it does a co hensive survey based on unrivalled clinical expe The well-known views of Mr Watson-Jones ma secure general agreement—he knows that many geons would be critical of the method he advocat treatment of fractures of the shaft of the femur that he tabulates such criticisms and answers t but they are stimulating views and above all or

Diseases of the Peripheral Arteries

Diagnosis and Treatment (2nd ed) By Saul S Sa M D London Humphrey Milford, Oxford Un *Press Pp 372 31s 6d*

In this edition Dr Samuels provides further ev of the value of conservatism in the treatment of per arterial disease , major amputation has been re in only one out of his 350 cases of thromboa obliterans, and this experience justifies the publ of the details of the therapy employed The doubts the value not only of surgery but also more elaborate physiotherapy which has been adv recently for obliterative arteritis, and confin attention almost entirely to stopping smoking, posture of the affected limb including postural ex hypertonic solutions by intravenous injection, a local application of mild antiseptics to gangrenous He makes useful suggestions for the treatment o the control of which is the most serious problem management of patients submitted to non-op treatment He attaches much importance to metry in the diagnosis and prognosis of per vascular disease, more especially when it is arteriosclerotic type , and certainly the method to be employed more extensively than it is at p Fuller after-history of feet which have healed Dr Samuels's regime would be welcome, and so clearer indication of the limitations of the method arteriosclerotic group At the end of the book th short chapters on Raynaud's disease, erythrome acrocyanosis, periarteritis nodosa, essential thr philia, embolism, cervical rib, axillary thro frostbite, ergotism and aneurysms, but the allowed has scarcely been sufficient to make the ac in any way comparable in value to that of o obliterative arteritis

THE LANCET

LONDON SATURDAY, MARCH 1 1941

WAR DOCTOR

THE rise of the Army Medical Service to its full tature in the last war was one of the landmarks in he history of medicine and a significant event in the fe of our people This is no mere rhetoric, no aporising of a self-conscious profession, but the calm udgment of public men who reviewed what had appened at the close of the war Speaking on une 8, 1920, to a great company met to do honour o the medical service of the Army our present PRIME INISTER urged his audience to imagine what it must ave meant to thousands of homes and hundreds of housands of men, in periods of the greatest human eakness and misfortune, to know that the great nass of suffering, misery and shattered figures which epresented war could cast itself upon the mercy of he Royal Army Medical Corps, never to find that nercy lacking Lord MIDLETON who presided emarked that this was the only occasion since the rmistice when a particular branch of the Army had een the object of public ovation And if further onfirmation is needed it may be found in the preface o the first chapter of the Medical History of the Great War which twice recalls "the singular reedom of the Army Medical Service from adverse riticism" when in previous wars the breakdowns n arrangements for the care of sick and wounded ave birth to masses of printed evidence in eports of royal commissions and parliamentary nquiries

How the transformation was brought about bears epetition It was SIDNEY HERBERT who after the Crimean War gave the lead in Army medical reform But nothing much was done until, as KEOGH used to ay, God sent the cause of medical reform two men—MIDLETON and HALDANE Lord MIDLETON gave the R.A.M.C the opportunity for postgraduate study which assured their scientific position Lord HALDANE had brought the regular medical officer into close ouch with the civilian branch of his profession MIDLETON on that occasion himself told the story There were, he said, men in that room who could emember the days when in a large cantonment the only site assigned for a hospital where capital operations were to be performed was a vacant spot between a dust-heap and a slaughter-house, and when the last man to hear of any intended move of the Army was the senior medical officer In every war up to that war the medical service had been hurried into the field, although starved in numbers for peace service insufficiently paid, without leisure or opportunity for scientific training, with scant opportunity for practising modern surgery, separated by a water-tight partition from the great civil profession which could be its only effective reserve But nowadays, he went on, the men who held the commands in peace were so chosen as to hold the same commands in war The equipment designed for peace was the same as the equipment for war The gap between civilian and professional soldier was so bridged over that the professional service could be developed into a national force Mr CHURCHILL, confessing himself as one who had in former days been Lord MIDLETON's critic, "youthful ignorant and hard," rejoiced in having the opportunity of saying that his work in reorganisation had been signally vindicated

What was true of the last war is true also of this, may be in even larger measure There has been little if any criticism of the teamwork of the Army medical department and when the carnage is over there will be thousands of soldiers and soldiers' families who will look back with quiet thankfulness on what their medical service did for them It is not from the soldier that the complaint may come but from the civilians at the front, for in bridging the gap between the civilian and professional soldier MIDLETON made it possible for enough of the profession to pass over on to the soldier's side to starve the civilian of medical aid—and this is what is happening It was MIDLETON's service to bridge the gap for one way traffic ; it may well be for a statesman of equal calibre to turn the bridge into a broad thoroughfare that can serve an all-in war Heretofore in its immediate medical preparedness for war the continental system had the advantage For a vast standing army the professional soldier's doctor is a necessity and he was segregated at an early stage in his career Chemistry and physics behind him, the French medical student who elected to go into the army entered the Val-de-Grâce where he learnt soldiering and doctoring side by side and became a medical soldier rather than a military doctor This was never the case here where medicine was more jealous of her essential nature and where six or seven years of the Hippocratic discipline deprived a man of any leaning towards other gods And happy for us that it was so, for the total war has knocked the bottom out of the continental system ; where every citizen is a potential war casualty it is a question of war doctor not soldier's doctor Nor is the exchange impracticable, or even difficult, in a country with a genius for solving problems as they arise True there are four services competing for medical personnel although, as we have said before, there is here no sordid clash of personal interest These medical services are responsible to four state departments, three of defence and one of health, and we do most urgently require a medical war cabinet, with executive power, to reconcile their needs (and perhaps those of the Dominions too) and to ensure that enough of the right men are in the right place, whatever may befall us Let the PRIME MINISTER, who is still youthful and even stubborn, but very knowing, let him give the medical services a common council, presided over by a man of his own choosing

SEDATION OF THE BOWEL

THE value of opium in checking diarrhœa has been appreciated for long enough, but only comparatively recently have we begun to understand the mechanism of its action The slow accumulation of knowledge has not been due to sloth ; on the contrary, a vast amount of published work bears witness to our

The Richest Natural Source of Vitamins B_1 B_6 and E

IT is now apparent that when Bemax was first introduced, twelve years ago, in order to combat the prevalent Vitamin B deficiency due to modern methods of "refining" food, the manufacturers were, in fact, building better than they knew For the increasing precision of nutritional knowledge has shown that Bemax is actually the richest natural source not only of Vitamin B_1 (aneurin), but also of B_6 (adermin) and of E (*a*-tocopherol) In addition, it supplies the other members of the B complex, and is particularly rich in assimilable iron

Thus the three vitamins which have been shown to play such an important part in the treatment of neuro-muscular degenerations and in maintaining the normal function and structure of the nervous system, exist together in their highest natural concentration in Bemax The value of Bemax for common constipation has long been recognised, and the physician will not overlook the importance of its high content of Vitamin E in cases of habitual abortion and sterility of dietary origin

The Vitamin and Mineral Constituents of BEMAX

	Approx daily *human requirement*	*One ounce Bemax supplies* *weight*	*% of daily requirement*
VITAMIN B_1 (aneurin)	mg 2 0 (666 i u)	mg 1 2 (400 i u)	60
VITAMIN B_2 (riboflavin)	2 0	0 9	45
P P factor (nicotinic acid)	5 0	1 1	22
VITAMIN B_6 (adermin)	?	richest source	100+
VITAMIN E (*a*-tocopherol)	?2 5-5 0	7 0-10 0	100+
IRON (available)	12 0	2 7	25
COPPER	1 8	0 45	25
PROTEIN, first class	gm 40	gm 9	22 5

Clinical sample of Bemax and literature sent to medical men on application to
Vitamins Limited (Dept L.J), 23, Upper Mall, London, W 6.

Other Products of Vitamins Ltd.

BEFORTISS
(Brand)
Concentrated Vitamin B

Tablets 200 i u and 2 mg per gm For high dosage of the B complex
Ampoules 2, 10 and 20 mg For high Vitamin B_1 dosage

FERTILOL
(*Wheat germ oil*)
Capsules
A highly active stable source of Vitamin E

For the treatment of habitual abortion, dietary sterility and certain neuro-muscular degenerations, etc

COMPLEVITE
Tablets
Vitamin and Mineral supplement

To make good the recently revealed deficiencies of vitamins and minerals in the average daily diet

PREGNAVITE
Tablets
Vitamin and Mineral supplement

To ensure an *adequate* supply of vitamins and minerals to meet the special requirements of pregnancy

RESEARCH IN GENERAL PRACTICE

In a story which gave many of us a thrill forty years o, "Ships that pass in the Night," BEATRICE ARRADEN wrote a charming parable It concerned man who from childhood had dreamed of finding the mple of the ideal which he thought was placed on the mmit of an almost inaccessible mountain After ars of effort he at last scaled the mountain to learn at this was not the place, the temple was in the lley he had left The practitioner who "has no portunity for research" might consider this tale n another page two general practitioners and an stetric surgeon have drawn some useful lessons from e analysis of their cases of breech labour Their mbers are small, but they show clearly that although is faulty presentation in no way affects the chances the mother it is a catastrophe for the child, and ey make out a good case for their conclusion that if rsion fails cæsarean section is the treatment of oice, especially in primigravidæ or where there is me degree of pelvic contraction Nothing spec- cular about the analysis of such records, none of the lendid ritual of white-coated priests inoculating ineapigs, not even the mysterious but impressive gebra of super-statisticians Yet it should be membered that the father of medical statistics was ity tradesman who knew no algebra at all, that in e enlightened 19th century it was not a highly ined "scientist" but a licentiate of the Society of othecaries who left general practice to create the st system of medical statistics in the world, and that e most original contribution to epidemiology of cent years was made by a general practitioner in ensleydale It is tempting to emulate Bishop ERKELEY's "Querist" and submit some interroga- ries Do we identify the technically difficult with the portant ? Do we think that no important truths n be discovered by simple methods ? Is it possible at if medical neighbours and friends pooled their perience discoveries might be made which had caped the Ministry of Health and the research units the teaching hospitals ? The times in which we re, when we are all thrown back on our own resources, d when so much is happening that the "experts" e too busy to record, sharpen the point of these estions In many ways we are forced to live more mply, to do without many things we thought were ecessary Intellectual snobbishness, reliance on perts, fear of doing simple things, might well be dded to the list of contraband of war

We must not underestimate the difficulties of the eneral practitioner when it comes to preparing his cords for publication His patients will not ppreciate the extra investigations and the thorough quiry needed to make a clinical case complete, gain, these things take time, and must be added to a aily round which may already be long enough, xamination of a stool in general practice is no simple atter of "Please send fæcal specimen to bact lab" n the bed-letter, but a complicated process, from btaining a specimen pot and instructing an amateur its use, to packing and despatching it to the boratory When all is done there is the writing up such a form as to catch the critical eye of some ditor But our peripatetic correspondent was dely wrong when he suggested last week that the edical journals look askance at such papers Alas that there are so few for them to look askance at Papers like that of Mr GAIRDNER and Dr and Mrs JACKSON are what we are in urgent need of, not only in obstetrics but in the whole field of medicine Many doctors in insurance practice, sometimes with the encouragement of the regional medical officer, have made records which have proved well worth the time expended on them and should be analysed for the benefit of the rest of the profession To get their full value, however, some pooling would be necessary, and here the R M O (when he returns) could help, as well as by initiating special inquiries For ailments outside the insurance sphere the stimulus might come from the hospital consultants One can foresee the time when the riddle of cramp, of gastric influenza or of neonatal hæmorrhage is solved by the Blankshire group

Annotations

MEDICAL TREATMENT OF FRACTURES

OPINIONS on the value of biochemical methods in accelerating the union of fractures and in the treatment of established non union vary between the enthusiastic and the dourly sceptical Surgeons in this country, who tend in the main to be conservatively attached to effective and continued immobilisation, will probably be a little suspicious of what C F and R C Nelson[1] term "the medical management of fractures" They describe the use of vitamins and hormones in the treatment of 1000 cases, the objective being primary healing with a minimum of callus The serum calcium and phosphorus were estimated at the outset by a simple technique in order to provide the basis for treatment, and it was found that the former was low in 85% of all recent cases Measures to raise the calcium content are advocated therefore whenever laboratory facilities are not available These measures include the giving of two pints of milk daily, the administration of calcium gluconate by mouth and subcutaneously, and the injection of parathyroid extract at intervals of a few days It is maintained that by these methods the serum calcium can be raised to the desired level, the effect being demonstrable within 10–15 days Should the serum phosphorus be low liver, eggs, fish and cheese are included in the diet and vitamin D is given in doses up to 3000 units daily The Nelsons point out that in normal cases vitamin D raises the phosphorus level unduly and delays union, it should never be given routinely but only in the 25% of individuals with an initially subnormal value During the period of treatment ♏15–20 of dilute hydrochloric acid is given with meals to facilitate the absorption of calcium and phosphorus from the bowel, and the urine must be kept acid throughout in order to avoid the precipitation of calcium in the urinary tract The object of this regime is to establish a serum calcium of 10 5–12 mg and a serum phosphorus of 3 5–4 mg per 100 c cm, and to maintain this 3 1 ratio For the simple Colles fracture and comparable injuries dietary methods only are employed, and where late absorption is feared, as in fractures of the femoral neck, dietary control is continued for many months In suspected acromegaly or myxœdema, or when the basal metabolic rate is low, thyroid extract is given, and iodine is administered to thyrotoxic cases The American workers claim not only to have prevented non-union in recent cases but to have effected sound union in delayed cases even without strict immobilisation However, their series lacks controls and no reference is made to the mechanical and vascular factors in the process of healing In this country R T Stirling[2] has given some attention to the biochemical aspects of diligence in seeking the explanation of this phenomenon For many years the issue was confused by the workers who could not see beyond the depressant effect of morphine on the central nervous system They assumed too readily that the constipation following morphine must be due to depression of the bowel resulting in diminished peristalsis From faulty premise to prolixity is an easy step, and it is significant that by 1920 UHLMANN and ABELIN[1] were able to quote no fewer than 314 contributions to the controversy that was still raging over the mode of action of morphine on the bowel

The earlier workers in this field held that the alkaloid acted by depression of the reflexes arising in the plexuses of Auerbach and Meissner NOTHNAGEL[2], on the other hand, postulated central stimulation of the inhibitory splanchnic fibres Other investigators failed to confirm that depression of the bowel actually occurred, and some unexpected observations were made, notably that morphine still produced constipation even when the extrinsic nerve-supply to the bowel was severed, and, far from depressing the bowel-wall, experiments on excised intestine showed that the predominating effect of morphine was stimulation [3] In retrospect it seems curious that the dispute should have lasted so long, when such broad hints as to the probable explanation were contained in the already published researches on the effects of this alkaloid on the stomach Thus, ZEHBE[4] as early as 1913 demonstrated radiographically in man persistent closure of the prepyloric ring after the administration of morphine, and, working on animals, MAGNUS[5] had demonstrated the same action in 1908 Despite the excellence of MAGNUS's pioneer work in this direction, he may now be accused of drawing a red herring across the path by his suggestion that the most important factor in morphine constipation was the hold-up of food at the prepyloric ring That this is a contributory cause cannot be denied, but it remained for PLANT and MILLER[6] to demonstrate conclusively the nature of the stimulating effect of morphine on the bowel in dogs and in man, and to prove that this action is the main cause of morphine constipation In dogs their results were obtained by experimental methods involving the use of the Thiry-Vella fistula, in man their observations were made on patients with thin-walled herniæ of the abdominal parietes, and by noting pressure changes in permanent fistulæ After hypodermic injection of morphine there is a great increase of tone in the small intestine and a simultaneous rise in peristaltic and segmental activity The augmented propulsive movements last only about half an hour and thereafter they are depressed for several hours In man the resultant effect of these changes is intestinal stasis Except where there is idiosyncrasy to the drug spasticity of the bowel dominates the pharmacological picture, and the passage of the intestinal contents is consequently hindered despite the initially enhanced peristaltic activity The diarrhœa which not infrequently occurs in dogs and which is a rare manifestation of idiosyncrasy in man is probably explained by a fleeting preponderance of the increase in peristaltic activity over intestinal spasticity

Although these results have helped to clarify our views on the main pharmacological actions of morphine on the alimentary canal, there remain for solution many minor problems Of these, the study of morphine-atropine antagonism is interesting to the laboratory worker and not unimportant to the clinician The evidence in favour of a purely local action of morphine on the small intestine includes the statement that increased tonus persists even after atropinisation It now appears that this applies only to small or moderate doses of atropine, for more recent work by KANAN[7] and by GRUBER and others[8] reveals that large doses do abolish the intestinal spasticity produced by morphine According to ADLER and IVY[9] the triple stimulating effect of morphine on the ileum is seen also in the colon, but morphine atropine antagonism is apparently not so complete in this part of the bowel The propulsive movements produced by morphine in the colon can be abolished by the previous administration of atropine, and by careful adjustment of the proportions of the two drugs both the propulsive and non-propulsive side effects of morphine can be eliminated without interfering with the increased spasticity of the colon At their face value, these findings suggest that there is some justification for using atropine as an adjuvant to morphine when intestinal quiescence is desired Variation in the susceptibility of different species of animals to drugs accounts for the heavy dosage of morphine and atropine used in the experiments on dogs (the corresponding amounts for a man of average weight would be about gr 1 of morphine and gr $\frac{1}{60}$ of atropine) These experimental results must therefore be regarded only as pointers, and the next step is to test their applicability to man And here it must be emphasised that not only are there often unexpected differences between human and animal pharmacology but where the vegetative nervous system is concerned responses to drugs are sometimes amphoteric, that is to say, the response can be reversed by altering the dosage [10] In this connexion, the experimental work of UHLMANN and ABELIN[1] is of special importance for they showed that while large doses of morphine increase the tone and contractions of the intestine very small amounts reduce both forms of activity Whatever may be the explanation of this, it seems that work on morphine-atropine antagonism is reviving uncertainty as to the relative importance in the genesis of morphine constipation of the intestinal muscle on the one hand and the nerve supply of the bowel on the other The researcher in this sphere is indeed compassed about with a multitude of exasperating difficulties, more particularly if he confines himself to observations on animals There is much to be said for following the example of PLANT and MILLER who supplemented their laboratory findings with observations on patients in the surgical wards

1922 cases, as were also prostration, anæmia and sting Hæmorrhage under the nails, noted by Sheldon the present epidemic, was not observed in 1922 In 22 the sausage was proved to be the criminal and it is ely to be convicted again this time In pigs the iscles chiefly invaded by the parasite are the diaphragm, ercostals and neck muscles, all of which are com-nly used to make sausages In Wolverhampton busy men eat sausage meat raw in Milford Haven 19 years thirteen infected people ate sausages obtained from particular butcher His pork was raised and slaugh-ed locally, but the farmer who had supplied the lucky pig was not identified At Harpenden the source the infected pork is still uncertain This week cases ve been reported in two districts of Cumberland

One of the chief features of this disease is muscular in and stiffness, and patients may therefore be king treatment for "rheumatism" and may on that ount be mis-diagnosed unless a blood count is done sinophilia is likely to occur towards the end of the first ek and to persist for about six weeks, and recent cases this outbreak have shown 20–70% of eosinophils

HE CONSTITUTIONAL FACTOR IN BEHAVIOUR DISTURBANCE

In assessing the relative importance of environment d constitution in the causation of such abnormalities of haviour as are seen in the psychoneuroses, in subjects th psychopathic personalities, and even in the ychoses, psychologists have been hampered by lequate criteria of constitutional defect It is true t gross somatic signs of degeneration are often present, ticularly in the shape of the face and head, and that etailed family history often gives a clue to causation, t even so the question of the hen and the egg arises most instances environment has played a precipitating t, and some people remain normal only through the bility of their surroundings and the sympathetic skill h which their lives are controlled by others The ctroencephalogram has brought to hand a new index abnormality Cerebral dysfunction—whether caused gross damage, by such agents as intracranial tumours scesses or the toxæmias, or by more subtle states, such the changes underlying epilepsy or the genetic erration in the members of an unstable stock—is sociated with abnormally slow alterations in cerebral ctrical potential which can be readily recorded and easured Lindsley and Cutts[1] have produced further nvincing evidence of the important part played by nstitutional defects in the causation of even the milder ades of behaviour disorders They have taken groups normal children and intelligent healthy adults and have ntrasted their electroencephalograms with those of a oup of 50 behaviour problem children, and of 30 ildren whom they considered to be constitutionally ferior The behaviour problems were sufficiently finite for the children to be admitted to a special spital, and included such things as irritability, restless-ss, temper tantrums, lying, stealing and obscenity ding to unmanageability in the home and delinquency the community The 30 constitutionally inferior ildren were wards of the state who were found to be placeable in foster homes, and who had a poor biological d social heritage By studying the characteristics of fferent groups of abnormal waves in the electro-cephalogram, Lindsley and Cutts found a great eponderance of abnormality both in children with own behaviour disturbance and in those who were nstitutionally inferior For example, while only 3% the normal adults and 30% of normal children showed ore than 5–8 waves a second, 80–90% of the abnormal ildren gave readings above this level Thus abnormal ctroencephalograms were three times as common in ildren with abnormal behaviour as in normal children

This suggests a disturbance of cerebral function which may be important in preventing the abnormal groups from adjusting themselves to their environment particularly if conditions are adverse Similarly, we might expect that the so called normal children who showed evidences of abnormality in the electroencephalogram would be relatively poorer risks in the face of persistent environmental difficulties

MECHANISM OF THE CARPUS

The mechanical anatomy of the carpus has lately been worked out by MacConaill[1] The capitate and hamate move together, as do the lunate and triquetral, while the scaphoid moves sometimes with one row and sometimes with the other The other bones can be excluded from the discussion He regards the capitate as the fixed bone in all movements In dorsal flexion the lunate slides round the capitate and the radius slides round the lunate in even greater degree In the movement from full volar flexion to full dorsal flexion the scaphoid moves on the capitate until the hand is straight, but after this position has been passed these two bones remain fixed while the lunate moves on them both This locking together of the scaphoid and capitate is of supreme importance MacConaill says that the proximal articular surfaces of the hamate and capitate form a screw surface so that in dorsal flexion the scaphoid and lunate are also brought more closely together In fact the bones of the carpus are welded together in dorsiflexion and more loosely packed in volar flexion These observations become of practical value in relation to dislocation of the lunate The methods of reduction that have been advised in the past, apart from operative reduction, are either simple traction or dorsiflexion followed by volar flexion If MacConaill's concept is correct, reduction should be more easily achieved by volar flexion followed by dorsiflexion and this is the method he recommends The movement of volar flexion draws the carpus over the dislocated lunate bone Slight traction on the hand helps this but only the very gentlest pressure on the lunate is required One minute only is needed for recent dislocations The movement of dorsiflexion then retains the bone in its reduced position, and this is the position of the subsequent plaster Late cases will require operative treatment, for in them the space that the lunate should occupy has been partly filled with fibrous tissue Nine cases, six of which had an associated fracture of the scaphoid or triquetral, have been treated by this method with excellent results

REACTIONS TO T A B VACCINE

The case for active immunisation of the civil population against enteric fever has been much discussed in recent months, and despite an official caveat that there were no strong grounds for widespread immunisation many local and hospital authorities have undertaken the inoculation of certain classes of the community against both enteric fever and tetanus One of the objections raised to T A B vaccine is that the local and constitutional reactions which follow the injection result in considerable loss of working time—perhaps more than vaccination would save by preventing enteric fever among an industrial population T A B vaccines may vary in their toxicity, and clinical comparisons of the immunising properties (as measured by agglutinin-formation) and toxicity of different commercial preparations are needed There is no reliable evidence that the use of detoxicated or oral vaccines to avoid reactions gives the same degree of protection as a crude vaccine of the whole organism, but care should be taken to use a mouse-virulent strain of *Bacterium typhosum* *Bact paratyphosum* C is added to certain vaccines, though infections with A and C are extremely rare in this country, and this T A B C vaccine should not be

Lindsley, D B, Cutts K K *Arch Neurol Psychiat* 1940 44, 1199

[1] MacConaill, M A *J Anat* January 1941, p 166

fractures, and has suggested the prophylactic use of vitamin C in the avoidance of excessive weak callus He does not consider, though, that hormones are of proved value in the ordinary case and attributes the vast majority of instances of non-union to imperfect reduction and faulty immobilisation Nevertheless, the paper by the Nelsons reminds us that there is a chemical as well as a mechanical side to the healing of fractures, and suggests the value of more frequent estimations of the serum calcium and phosphorus in selected cases Where in the absence of some gross endocrine disturbance a significant deficiency is found their regime might be worth trying

NUPERCAINE SPINAL ANÆSTHESIA

ON a total experience of 500 cases Hand and Sise[1] of the Lahey Clinic in Boston and Rapoport[2] of New York speak highly of Nupercaine for spinal anæsthesia, and those in England who are familiar with the drug, under its name of Percaine, will agree These American workers used only the hypobaric 1 1500 solution Nupercaine is readily soluble in water and alcohol, and has the advantage that it may be boiled repeatedly without decomposition An important practical point is that the drug precipitates as a free base in even slightly alkaline solution, and this is indicated by cloudiness Syringes and needles to be used for nupercaine should therefore be washed out immediately beforehand in sterile water acidified with a few drops of acetic acid, or in 1 c cm of the 1 in 1500 solution itself which has a slightly acid reaction Hand and Sise have used the drug in two main groups of cases—for upper abdominal operations expected to take a long time, and for operations in which for positional reasons hypobaric rather than hyperbaric solutions are required They favour fairly heavy premedication, the average adult being given gr 1/3 of Omnopon and gr 1/150 of scopolamine subcutaneously 2 hours before operation and gr 3 of Nembutal by mouth an hour before operation The patient therefore arrives in the operating-theatre very sleepy Just before the spinal anæsthetic is introduced 50 mg of ephedrine sulphate is given intramuscularly The dose of nupercaine is simply calculated from the height and sex of the patient For upper abdominal anæsthesia the injection is made in the 2nd lumbar interspace, 5 c cm of cerebrospinal fluid is discarded and the nupercaine, warmed to or slightly above body temperature, is then injected at 0 5 c cm per sec The injection is made with the patient lying level and on his side and he is then turned face downwards Nupercaine is effective in very dilute solution and its anæsthesia lasts a long time For upper abdominal surgery it gives excellent muscular relaxation, anæsthesia develops within 4–12 min of the injection and lasts for 2–3 hours Supplementary general anæsthesia is valuable in many cases apart from those where the operation is prolonged beyond the duration of the spinal anæsthetic, " to lessen the technical surgical difficulties and to alleviate mental and physical discomfort to the patient " Hand and Sise describe nupercaine as having little or no depressant action on the cardiovascular system and note that " when the changes in blood-pressure occur they are usually sudden and marked, are associated with nausea and retching, and appear to be initiated by manipulation of and traction on the abdominal contents, chiefly in upper abdominal operations " In their experience the early employment of supplementary general anæsthesia (either cyclopropane or intravenous Pentothal) prevents the fall in blood-pressure due to intra abdominal manipulations A rare complication is sudden unconsciousness as the patient is placed in the initial prone position, presumably due to cerebral anæmia, this can be rectified by intravenous injection of a cardiovascular stimulant, for example pitressin and ephedrine Both Rapoport and Hand and Sise use nupercaine spinal anæsthesia largely for " poor risks," but in this country many anæsthetists hold that spinal anæsthesia is best avoided in shocked and toxic patients

The great variety of trade names which may be given to the same drug in different countries is a perpetual source of perplexity to medical men, and makes it unnecessarily difficult to keep abreast with the current literature Here is a case in point on which we have already commented[3] The confusion of percaine with procaine (Novocain) has been known to lead to a fatal issue, though both are safe spinal anæsthetics when given in the correct dose and proper manner The general adoption of the name nupercaine would clearly be an advantage, and there is a good case for the adoption by the various drug supply firms of a single name for each individual drug wherever it is marketed

TRICHINIASIS IN 1922 AND 1941

THE last outbreak of trichiniasis in England was at Milford Haven in 1922, and it is of interest to compare it with the one now in progress at Wolverhampton and Harpenden *In 1922 there were only 13* cases, compared with the 500 already estimated by Sheldon to have occurred in Wolverhampton[4] The diagnosis was made at Milford Haven on the eosinophilia and on the discovery, in two cases, of *Trichinella spiralis* parasites in the fæces The examination was carried out on fairly thick films which were pressed between photographic plates and examined under a very low power Embryos have been isolated from fæces in the present epidemic by Prof R T Leiper, but the diagnosis was originally established by biopsy of muscle, a method which does not seem to have been used in 1922

The eosinophilia in the 1922 epidemic ranged from 15 7 to 39 6%, at Wolverhampton the eosinophil count has been less characteristic, ranging from 1 to 49% in seven cases reported by Lee[5] His figures show that the eosinophil count may vary widely at different stages of the same case—in one from 3 to 33%, in another from 49 to 5% At Harpenden the figures have been steadier ranging, in five cases reported by Garrod and MacLean[6] from 27 to 47% The clinical features of the 1922 epidemic were similar to but not identical with the present ones Patients in 1922 showed gastro intestinal disturbance and epigastric pain at the onset, with vomiting and diarrhœa, in the present epidemic gastro intestinal symptoms have been largely absent, and constipation is the rule, but vomiting has occurred in about a third of the cases towards the middle of the illness In typical cases of both epidemics, an early symptom noted by the patient was swelling of the eyelid and headache Among the 1922 cases the conjunctiva was sometimes red and œdematous, and in the present epidemic the conjunctiva sometimes protrudes through the closed eyelids " as a bulbous watery mass " Muscle pains appear to have been severe in this epidemic, sometimes amounting to agony (three women claimed to prefer labour pains), in 1922 patients noted especially the pain of changing from one position to another, and one man, whose diaphragm was probably affected, complained of great pain in the chest Cough has been a symptom in the recent cases, but in 1922 there was no evidence of lung involvement, there was, however, dyspnœa on movement Signs of damage to the central nervous system were common in both epidemics, varying from transient paresis or depression to severe delirium or signs of a cerebellar lesion Some of the present cases have simulated meningitis, in others the patients have been mentally lethargic and sleepy, this contrasts with insomnia which was a distressing symptom in most of

THE EMERGENCY MEDICAL SERVICE

AND THE FUTURE*

By JOHN B HUNTER, M C, M Chir Camb F R C S
RGEON TO KING'S COLLEGE HOSPITAL AND THE ROYAL CHEST HOSPITAL, LONDON, GROUP OFFICER, E.M.S

EARLY in 1939 representatives of the staff of the ondon teaching hospitals met under the title of the ospitals War Committee and decided to ask the oluntary Hospitals Committee to combine with them ıd meet the Ministry of Health to hear what arrangeıents were being made in connexion with the medical rvices if war should break out The Ministry thereupon put forward their sector scheme whereby twelve embers, one from each of the teaching hospitals, should e selected to advise the ministry on hospital arrangeıents in the London area and link the teaching hospitals its casualty scheme England had been divided into idependent regions, each with its own commissioner iperintending all services and a hospital officer to al with the medical problems London presented special problem on account of its size and vulnerbility, and the fact that it had so many hospital beds proportion to those in the home counties A rough nsus of the beds available and buildings suitable for se as hospitals outside London had been made

EARLY PLANS

The Ministry of Health were relying on their hospital fficers to coördinate the arrangements in each region, aking use of the county medical officers of health as eir agents The introduction of the sector system in e London region complicated the picture, and naturally e medical officers of health must have questioned the pearance of those strange creatures, the group officers, their pond, but their goodwill overcame many fficulties The buildings outside London earmarked r use as hospitals were then carrying on their peace-ne function, so that new theatres, X-ray departents and nursing-staff accommodation remained paper hemes and with few exceptions were not started before ar broke out In September, 1939, when these hostals were required, staff quarters were short or uncomrtable, and essential services were inadequate It is fficult to know how this could have been altered, unless e hospitals had been put on a war footing six months more before war broke out It was soon clear that the umber of beds provided would be inadequate if the gure of casualties given by experts was taken as a guide hose figures, we know now, were too high but we had legislate for them Existing beds in provisional ospitals were inadequate, and the Ministry decided to ut up hutted hospitals, using in most places the adinistrative services of existing hospitals or institutions his work was put in hand at once The huts were not ady until after war had broken out, and a second pansion of hutted hospitals was delayed by difficulties obtaining material Groups of beds, or individual uildings, were also earmarked as special centres or ospitals

EQUIPMENT, STAFF AND TRANSPORT

Lists of surgical instruments for a casualty service ere prepared, no attempt was made to provide aborate surgical equipment For years past surgeons ad been using nothing but hand-forged instruments, ıd the surgical instrument makers of the country were able to supply suddenly large quantities of massoduced instruments and to meet at the same time e requirements of an expeditionary force

X-ray apparatus, too, fell short of requirements for e expanded number of beds It was decided that most ospitals would have to be served with portable machines cause it was thought to be impossible to move fixed achines out of London in time Later, plans had to made to house fixed sets, obtained not only from anufacturers in this country but also in America By the generosity of the voluntary hospitals especially those of London, large amounts of equipment were made available Transport was already planned, not only to take casualties from the scene of the incident, but also for inter-hospital evacuation, and these plans are in operation today

Lay staff of the emergency hospitals included expert staff (such as theatre porters and technicians), and domestic staff and porters Expert staff had to be provided from the voluntary hospitals domestic staff and porters by the local authorities owning the hospitals It was clear that nursing staff for the increased number of beds could not be provided on a peace-time basis, and that even on a reduced scale there would be shortage—as has proved to be the case Sector matrons were appointed and a pool of nurses from the various hospitals was made, including the London County Council hospitals These were allocated to the emergency hospitals, together with members of the Civil Nursing Reserve a new body enrolled as a war time measure Outside London the arrangements for nursing were in the hands of the regional hospital officers and the county medical officers of health

In appointing medical staff a rule-of-thumb method could be employed for house-officers but not for more senior grades From time to time the group officers pressed for the medical staff to be embodied in the territorial service, but these recommendations were not favourably received The group officers in the London sectors considered that as the question of remuneration for medical staff affected the whole country, it should be determined by a committee set up by the ministry, in consultation with the advisory committee For many months the question caused much uneasiness and discussion

THE PROOF OF THE PUDDING

All the experience of the Ministry of Health had been associated with peace-time health problems, and their only contact with hospital affairs had been through the county medical officers In starting this new service they harnessed it to existing civil practice, including the voluntary hospital system But there was bound to be some rigidity—a bureaucratic tendency to procrastination that to many people appeared unforgivable

When the service came into being the upgrading in the hospitals was at once begun, and medical and nursing staff reported to their hospitals The staffs of the London hospitals had uprooted themselves and they found themselves in strange surroundings Their clinical work had disappeared, and the theatres and wards among which they found themselves appeared rudimentary, with almost complete absence of those efficient arrangements which were part of their life But they started with goodwill to reproduce in these new hospitals a replica of the old, and their criticism was chiefly constructive

No civilian casualties appeared, there was a lull, and the civilian sick returned to the outpatient departments of the hospitals and arrangements had to be made for their treatment The ministry decided to transfer cases requiring treatment into the sector hospitals These hospitals were not equipped for such work and the influx of civilian sick led to further improvement in the equipment of all departments, and this process still goes on

Certain hospitals were earmarked as convoy hospitals, and to these the Army sick were brought from France, but it was not until the Germans invaded the Low Countries that any wounded were received, and not until the retreat did the service have to deal with large numbers of wounded The work was well done but some medical officers were not aware of the facilities of the service, they had the feeling that if a case came into their hospital it was up to them to treat it, and see it through, rather than to have it transported to another hospital further afield where there was less crowding and perhaps better facilities for special cases

In August and September civilian casualties had to be treated, so that the purpose for which the service was created was at last fulfilled Despite the fact that large numbers of hospital bed were put out of action by bombs, no undue strain was put on the numbers remaining, the emergency hospitals were even able to go on treating the civilian sick confused with the typhoid and cholera vaccine, which as suggested in our issue of Feb 15 (p 234) might be known as "T A B Chol" vaccine

---

* Based on a presidential address to the section of surgery of the Royal Society of Medicine given on Feb 5, 1941

Dr Maurice Williams,[1] medical officer of health for Southampton, was among the first to use T A B vaccine on a large scale to protect the civil population, and he has now reported an analysis of the reactions and loss of working time amongst large groups of male and female manual and sedentary workers Only 30 working days were lost among a total of 10,032 persons after a first dose of the Lister T A B C vaccine (0 3 c cm for women and 0 5 c cm for men) Among 1872 male manual workers there was no time lost, although 27 2% of them had combined local and general reactions It is not stated whether or not an effort was made to inoculate mostly at the week end Combined reactions were most frequent among male sedentary workers, 2782 of whom lost 15 working days Female manual and sedentary workers were much alike in the proportion of local and general reactions and in time lost It was noted that those with severe general reactions usually had mild local reactions, but the paucity of reaction in this mass-inoculation of an industrial population should help to lay one of the bogies of the T A B vaccine

THE DISCOVERER OF INSULIN

Sir Frederick Banting, F R S lost his life when the aeroplane in which he was pursuing his research work crashed in Trinity Bay, Newfoundland So ends nobly a meteoric career of great service to suffering humanity The discovery of insulin in 1922 was not an isolated brain-wave, but the painstaking push to a successful issue of a train of thought started thirty years before by Minkowski and Mering when they showed that the pancreas must have an internal secretion dealing with sugar in the blood as well as an external secretion dealing with foodstuffs in the gut But this internal secretion of the islands of Langerhans eluded them as well as Schafer who called it insulin without being able to isolate it The dead pancreas continued to guard its secret although in 1908 Zuelzer and Scott extracted small quantities of an active substance which proved too toxic for human use But Banting was not to be baulked by the failure of others from securing so glittering a prize Macleod's department in Toronto had given him a new technique of estimating minute changes in the blood-sugar Best's skill enabled him to block the external secretion in dogs and recover from the still intact islands an extract which cured experimentally diabetic dogs Armed with this confidence Banting and Best quickly verified the suspicion that the insulin was there in the dead pancreas all right and could be extracted with alcohol before its destruction by ferments And finally Collip purified the extract from its toxic constituents so that it could safely be given to patients It all seems so simple now—the relentless pursuit of truth to its logical conclusion Banting deserves his place in the long gallery of those who have found a remedy for disease, he is one of that smaller band who found a talisman which may open other doors

BLEACH CREAM FOR THE MAN IN THE STREET

THE Minister of Home Security has sent letters to local authorities asking them to request the help of all pharmacies in Great Britain in a scheme for making bleach cream available for members of the public if the enemy uses blister gas The scheme is a simple one The proprietor of each pharmacy, having been provided by the local authority with two enamel pails and 14 lb of tropical bleach, is to be asked, as soon as gas is used, to mix bleach cream in the pails, and if blister-gas is being dropped in the vicinity to place the pails of cream on the pavement outside his shop with a poster instructing the public how to apply it It has been agreed with the Pharmaceutical Society, whose ready collaboration the Minister of Home Security acknowledges, that pharmacists should be asked to perform this service without payment, as part of their contribution to the national effort The Minister's letter says "Gas has not been used and the scheme is therefore precautionary only It has been decided to ask pharmacists to cooperate because they possess the necessary technical skill for making the cream and their pharmacies are well spread over all populous areas" It is also stated that anti-gas ointment No 2 (chloramine) is now available for commercial sale at controlled prices from manufacturers who have received special permission from the Ministry As supplies become more freely available, it is hoped that pharmacists will stock this ointment, but it cannot be expected that more than a limited proportion of the public will ever be able to buy their own supplies The scheme for bleach cream i a supplementary safeguard

ENDEMIC FLUOROSIS

IN a leading article on p 216 of our issue of Feb 15 we were able to give first-hand information about the distribution of fluorine-bearing minerals and how the fluorine may find its way into drinking-water or into the fumes from kilns and so give rise to signs of fluoro in man and animals The geological information was supplied for publication by Mr C N Bromehead w the permission of the director of the Geological Survey and we regret that no acknowledgement of its source appeared in the article The evidence is noteworthy connecting, for the first time so far as is known, the incidence of fluorosis with the nature of the subsoil of th country

A WORKING DAY

THE gipsy strain in mankind gives little encouragement to those who try to regiment us The eight hour shif so just and symmetrical on paper, gets anything but a warm reception from those who are invited to work it Miss F Isabel Taylor, senior deputy chief inspector of factories, reports[1] that when workers had a choice between the two eight-hour shift system and long hours on a single shift, the single shift was generally chosen One reason for this is that people dislike coming on duty at unorthodox times Eight-hour turns are apt to beg at 6 A M and 10 P M, workers—anyhow, at the beg of the war—disliked going about the dark and streets at these hours Again, the eight-hour shift meant a loss of money which would otherwise be earne for overtime, and which was welcome in families wher incomes had been reduced by the recruitment of youn men Sometimes, too, there are insufficient workers in a district to make up even two—much less three—eight hour shifts, and, even where ordinary labourers plentiful, skilled tool setters and other key men scarce, so that it was simply not practicable to two or three shifts instead of one Where long had to be worked, people preferred some long days some short days rather than an arrangement of which left no evening free for shopping or a visit to cinema They even preferred to spend only 10 or minutes over tea, and get home a quarter of an earlier, rather than to take the regulation half hou Perhaps some of them are biologically right in pr variety and dash to ordered regularity The fac hand is probably in greater danger from the effects monotony than is any other kind of worker, and if knows a way to make his life satisfying and various ought to be able to take it

We regret to announce the death on Feb 19, after a accident, of Mr THOMAS HELMER, L D S, deputy secretary of the British Dental Association, at the age of

News also reaches us from America of the death Holland on Dec 16 of EUGEN DUBOIS of Leyden the early 'nineties Professor Dubois discovered canthropus, the famous "missing link," in Java dmitted in place of *Valeriana officinalis* which can be ollected in England from both wild and cultivated lants but was formerly obtained in large quantities rom Belgium and Holland. The opportunity has been aken to make a correction in the official dose of mepacrine hydrochloride; this should read: metric 0·05 to ·1 gramme; imperial ¾ to 1½ grains.

---

[1] Annual Report of the Chief Inspector of Factories for the 1939 London H M Stationery Office, 1s, p 37

While it is gratifying that India is able to supply this ountry with vegetable drugs which were formerly btained mainly from countries which are temporarily losed to our trade, it seems curious that we should have o bring a commodity like valerian such a long distance verseas when all our domestic needs could be supplied n our own country if production, collection and distribuion were carefully organised. It may be that by next utumn when the rhizomes of the plant cultivated in Derbyshire, Oxfordshire, West Suffolk and elsewhere in England are ready to be dug up there will be less need to use cargo space for a drug which grows under our very noses. Incidentally belladonna and dandelion root are also being imported from India in order to make up for he loss of imports from central Europe; what has been aid about the home production of valerian applies almost equally to these.

THE STRETCHER PATIENT SECURED

A R P workers sometimes need to lower a patient on stretcher feet first by means of a rope fastened to the ead of the stretcher and a guide rope pulling the foot nd out from the wall, or to lower him by sliding the retcher down a ladder, or to lower him horizontally om an improvised crane, with the chance that the retcher will hit projections on the building and be tipped n one side or up at one end. Mr H F Hodges, staff fficer for stretcher parties, and Dr E B Grogono, nedical officer for civil defence, at Wanstead and Woodord, have devised a method of securing the patient to he stretcher by means of seven triangular bandages, and his is said to ensure that, whatever the position of the tretcher, the patient will not move more than 2 in. in ny direction and that he will even remain in contact ith the stretcher when face downwards.

The patient is blanketed (the Wanstead and Woodford nethod officially approved,[1] is preferable), placed on the tretcher, and the bandages are then applied as shown n figs 1 and 2. They are secured not by reef knots, which for this purpose are useless and dangerous, but by two round turns on the stretcher bar and two half hitches (fig 3); this has the advantage of taking nearly all the strain off the knot itself. It does not matter whether the knots are tied as a clove-hitch or in opposite directions. Whether the head or the foot of the stretcher is raised nearly all the patient's weight is taken by the ankle bandages. The knee bandage prevents flexion at the knee, which would allow the patient to sag downwards, and the hip bandage steadies the pelvis. The crossed chest bandages give support if the stretcher is turned on its side and also take a little weight if the head is downwards. They can be fairly firmly applied and scarcely restrict breathing. The head bandage immobilises the skull comfortably and does not normally take much weight; it is especially useful if the patient has a head injury. Alternative methods have been devised for special injuries. For example, with leg injuries, two bandage slings are placed under the arms from the top bar of the stretcher (fig 4); the pelvic bandage is used, but the weight-bearing ankle bandages are omitted or modified, and the legs are steadied on the stretcher by such means as the injuries allow. These methods have been approved by rescue personnel and are now being practised. With custom, the bandages can be applied very quickly.

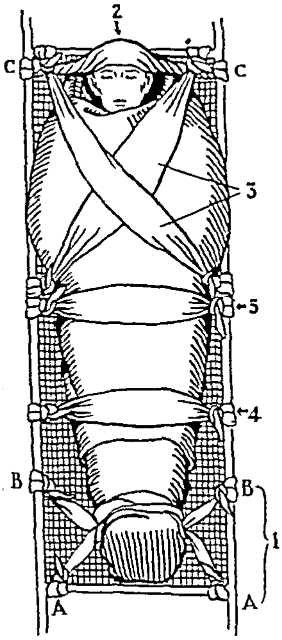

FIG 1—The seven triangular bandages applied. Numbers indicate order of moves

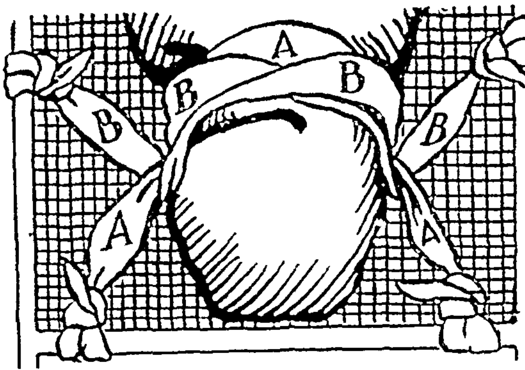

FIG 2—Detail of foot bandages

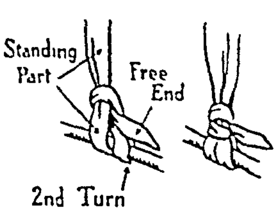

FIG 3—Knot

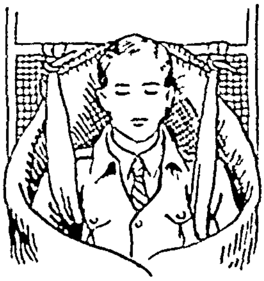

FIG 4—Arm slings

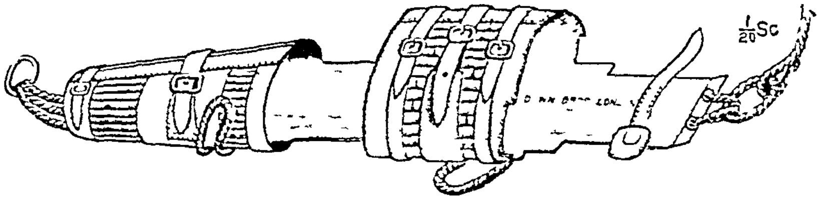

FIG 5—Neil Robertson stretcher, used for hoisting patients from the holds of ships

A ready-made stretcher intended to serve the same purposes, (the Neil Robertson hammock stretcher) is shown in fig 5. It has proved valuable in the Navy for removing wounded men from turrets or storeholds, or even from ship to ship. The bands which enfold the patient are made of canvas, reinforced with bamboos or laths, and fasten with adjustable straps; the stretcher is thus compact, light and flexible. The patient can be carried by the hand grips at the sides, or slung from ropes at the head and feet.

INDEX TO THE LANCET

VOL II, 1940

The Index and title-page to Vol II, 1940, which was completed with the issue of Dec 28, is now ready. A copy will be sent gratis to subscribers on receipt of a post card addressed to the Manager of THE LANCET, 7, Adam Street, Adelphi, W C 2. Subscribers who have not already indicated their desire to receive indexes regularly as published should do so now.

Some have seen the Emergency Medical Service as the beginning of a state medical service I do not think that this is true Nevertheless it soon became clear that a new conception in medical service had come into being The idea of decentralising the treatment of the urban sick was not new It had been advocated for many years—whenever one of the large London hospitals was due for rebuilding The reasons against removal included the difficulty of getting patients to consent to go out, because their relatives might not be able to visit them, and possible difficulty in connexion with the consulting staffs These have not proved insurmountable, the patients in the sector hospitals are still visited by their friends, and the consulting staffs have found that travelling to and from the sector hospitals has not been so difficult to arrange as was anticipated It seems that the principle of keeping a small hospital in town with an adequate outpatient department and transferring the sick to a hospital in a green belt outside is feasible The Minister of Health, from the work of the Nuffield Trust, has already seen the possibilities opened up by the regional system In the country districts enlightened counties have taken advantage of the Hospital Act which permitted them to set up an adequate hospital service, others have not been so forward and these have had to depend on small voluntary and cottage hospitals with insufficient accommodation The regions include several counties and borough councils, so that a new method of control will have to be evolved, the county control disappearing But it would be unthinkable not to use the enormous experience of the county medical officers and their staffs in any such scheme

THE FUTURE

The fallacy of all policies connected with medical services is the position, in the social scheme, of the doctor We have trained the lay public and ourselves to regard our position in the economic structure as that of a consultant We are there to give advice, and if they don't like it—whether it takes the form of plans for an operating-theatre or a bottle of medicine—they are at liberty to throw it down the sink Some change in this outlook will have to come Medical men will have to be given some kind of executive authority, and the medical profession will have to be ready and willing to assume that authority, so that medical measures for the improved health of the nation are not left to county committees

Let us sketch an outline of what such a regional scheme might look like There would be small hospitals with full outpatient departments in the urban districts, and, outside these districts, in a green belt, large central hospitals providing accommodation and facilities for all specialties, and dealing only with acute sick in the same way as the existing voluntary hospitals do Further afield, depending on geographical circumstances, there would be satellite hospitals dealing with tuberculosis, mental cases and those cases known as the chronic sick, and in each region there would be convalescent homes for children and adults Let us see how the hospital patient of today would fit into such a scheme A case of gall-stones or cancer would seek advice at an outpatient department and be seen by the appropriate consultant who would advise hospital treatment The case would be admitted centrally and transferred to the large acute hospital to one of the consultant's beds in that hospital After investigation and appropriate treatment the patient would be sent for convalescence, or if the condition was inoperable to his own home or to the satellite hospital for the chronic sick With another, a patient with tuberculosis, the same procedure would be adopted, he would be sent for investigation and treatment to the larger hospital or direct to the satellite sanatorium The acute case would be dealt with at the urban hospital, but the patient would be transferred to the periphery as soon as he was fit to travel

At this point undoubtedly someone will say this is a state medical service, and at once sinister thoughts creep in about the curtailment of that liberty for which we are supposed to be fighting I would agree that this would be a state service—a proper state service—but it would be no more than what the emergency medical service is attempting to be today with a free medical profession Such a scheme has to be harnessed to finance, and it is here that the profession become nervous, believing that money means not so much control as interference This need not necessarily be so In the past the medical schools have been given large grants of money through their universities, but there has been no interference with the way individual schools have carried on their affairs That the money granted has been expended in a proper manner is all the control that has been asked These grants merely ensure that a broad general plan is followed In the regional scheme outlined some similar system of linking finance might well obtain It has already been suggested that the voluntary hospitals might have their resources pooled under a hospitals corporation, on similar lines to the B B C Such a suggestion might go further by pooling all money that today goes to the hospital services, under a national medical corporation, or some such body

In such a scheme surgery would play a large part and the surgeons of today should be asking themselves how they can improve the surgery of the future in any reconstruction that takes place What constitutes a surgeon? Is he a man who goes out into a country district and calls himself a surgeon, or is he a man who takes a higher qualification in surgery? Broadly speaking, neither The first may fail from lack of knowledge, the second from lack of judgment He should be a man who in the opinion of his teachers has enough knowledge and experience to undertake surgery, who has served an apprenticeship in surgery The carpenter and the cabinet-maker work in the same medium, yet the one requires a different apprenticeship from the other, and we expect a more finished class of work from the latter We must ask ourselves, then, if these surgeons of the future should not have more experience under recognised teachers, after their final surgical examination, and before going out into the country under such a scheme We are seeing almost daily men and women with wounds that seem as though they must cripple the patient for life, who yet recover almost full function As surgeons we have also to inflict wounds in patients We should see to it that we do not take advantage of this astonishing phenomenon of human recovery, but recognise it humbly as an aid to our art and that we teach our assistants to treat it in the same way, so that when they leave us they go out with judgment and gentleness as good surgeons For our part we must see that, whatever reconstruction takes place when peace comes, the individual character of British surgery—which is one of its greatest possessions—is maintained

FURTHER AMENDMENTS TO THE B P

FURTHER alterations and amendments to the British Pharmacopœia have been effected by notice in the London, Edinburgh, Belfast and Dublin *Gazettes* The items concerned are acetum, oxymel and tinctura scillæ, scilla, cataplasma kaolini, sodii lactas, tinctura valerianæ ammoniata, urginea, valeriana and valeriana indica Hitherto the squill of the Pharmacopœia has been restricted to the bulb of *Urginea scilla*, the main source of supply of which was Sicily, and as that source has been closed Indian squill, the bulb of *Urginea indica*, is the subject of a new monograph and the monograph on squill has been amplified by the addition of the words "when squill is prescribed or demanded Indian squill may be dispensed or supplied" Facilities have been given to the importation of Indian squill which is now quoted in the London drug market This variety of the drug is stated in the B P C to be used in India and the Eastern Colonies in place of squill, and by amending the monographs on vinegar, oxymel and tincture of squill so as to permit the use of Indian squill in their preparation the Pharmacopœia is brought into line with Indian practice The effect of the alteration in the monograph on kaolin poultice is to sanction the use of sodium lactate in place of glycerin in its manufacture, the object being to assist in the conservation of glycerin supplies The monograph on valerian has been amended by the addition of the words "when valerian is prescribed or demanded Indian valerian may be dispensed or supplied" As in the case of Indian squill, facilities have been given for the importation of Indian valerian, and in the preparation of ammoniated tincture of valerian Indian valerian (*Valeriana wallichii*), which is indigenous to the Himalaya, veral periods allotted to a regular sergeant to instruct in the use of service forms, but his barrack-square nce prevented me, and lastly, I listened first with onder and then with admiration that my favourite bject—psychological medicine—should be dealt with two periods described on the time-table as neurology d should yet be handled in a manner which left the pression of first-rate specialist knowledge combined ith a practical, human point of view that I had not sociated with service medicine There was a glamour o about living in an officers' mess housed in an ex-othschild palace with a chandelier of a hundred lights anging from the high roof of the hall Solid gilt overed the richly moulded ceiling of the writing-room ad food of magnificence and plenty undreamt of by ny houseman was served in a panelled but still gilded ining-hall

There were, of course, the difficulties and anxieties hich I find inseparable from life among a large number f complete strangers, and there was the bogy of saluting Whom to salute and when? And how, when confronted y a long column of men "eyes-lefting" you? All that eems funny now but at the time it seemed complicated nd important Few of the new officers there could refrain om comparing their feelings with those they had xperienced as new boys at school With age and xperience we learn to control and conceal even from urselves most of our childish reactions, but when, I onder, if ever, do we really abandon them? From his training centre I went by ballot to a large recruiting epot Recruits arrived there at the rate of 200–300 a ay They spent three days in the camp queueing, they ueued up at different places all over the camp for clothes nd forms and photographs and food and medical nspections and inoculations These last fell to my lot Every man on arrival at and departure from a station has to be "F F I-ed" by an M O, that is, he is certified 'free from infection" In large camps the procedure is ighly organised, at this one the men were formed up, tripped to the waist, in a long queue I sat on a chair wo paces from the head of it, a corporal gave the order 'Drop your slacks to your knees and put your hands upon your heads as you come up to the medical officer" An orderly stood where he could see each man's back while I ran my eyes alternately up and down their bodies—this sort of work teaches you economy of movement—noting with interest those of exceptional physique and wishing for the sake of tidiness to group them into their physical types But how much more difficult it will become to treat people as individuals when civilisation reaches that degree of specialisation which requires only the appropriate physical type to be employed on each job uniforms already render the recognition of individuals in a group less easy, but we do at least still have the tall and thin mixed up with the round and rosy

Being ignorant of skins I usually had to learn from the airman the name and treatment of any of the unusual skin diseases I saw, but there were, I noticed, an unfortunately large number of men with, or severely scarred by, acne Occasionally a man had to be kept till the end for more careful scrutiny of a possible scabies and I was disturbed by the thought that I might miss what until a few weeks ago I had never seen—a case of pediculosis

I have not yet been able to overcome the feeling that I owe an apology to these young airmen for lending to an examination of this sort the title "medical" The custom, I suppose, survives from the days when all common soldiers were presumed to be lousy until the contrary was proved, but, needless to say, among the self-respecting and intelligent young men recruited into the Air Force today any untreated skin disease is extremely rare If one of these examinations made on changing stations should reveal unreported skin disease, it would be, I think, indicative of lack of confidence by the airmen in the medical service of the station concerned rather than neglect on their part

The technique of mass inoculations was still more highly organised As the most recently joined M O of a team of three I began by vaccinating while another gave the T A B and the third the A T T The men again filed through, this time as each passed the first orderly checked his name off a list, a second orderly cleaned his arm, and a third passed a sterile needle for each man to the M O who gave the first injection The man, with the needle still hanging in his arm to save a double puncture, walked on to the second M O served by a fourth orderly who filled the syringes and returned the used needles to the steriliser A fifth orderly flamed my vaccination needles and passed them to me with the end dipping in a phial of vaccine lymph, and as each man stepped up I had only to make one scratch "not exceeding ¼ in" and drop my needle mounted on its cork into a basin The man passed on to a sixth orderly who applied a dressing to his arm After the first parade my fingers and wrist ached, but I was proud of the speed and efficiency with which we had performed our task I forget now the exact figure, but I think we had got through the whole parade at the rate of one man per 7 seconds whereas the "record" was only 5 seconds per man It was not long, however, before my interest in whole men rather than their arms asserted itself, at first it was only an outstanding arm, one of magnificent girth or colour (for this was a summer of fine tanning) or, occasionally, of match-stick proportions which compelled me to look and see what manner of man it belonged to, but with even a single glance I fell behind with my work and before long I revolted at the system These mechanised contacts between doctor and patient are bad for both, tending to weaken the bond of personal confidence which is needed if one is to see disease early and treat it effectively The whole business reminded me of a modern factory I was once shown over in Denmark where the sides of bacon passed on an endless chain before a team of white-coated inspectors each of whom nonchalantly applied to its rind his appropriate stamp

* * *

Correspondence on war neuroses had not prepared me for Mr H F Buxton's story of his blasted horse, Idol, who seems to have behaved like an old-fashioned shell-shocker After the bang, which just makes fourteen of his mates frightened and restless, Idol and another horse lie unconscious The other recovers in two hours, but Idol is dead to the world till a humane killer is brought along, when he suddenly shivers and gets up, returning with some difficulty to light duty at the end of a week Three months later comes another bombing, more severe this time, and Idol relapses in typical fashion, now he cannot back as a well-disciplined dray-horse ought, and finds difficulty in turning—interferences with voluntary movement which, in the human hysteric, would demand a search for purposive or symbolic elements in the depths of the unconscious, or, according to another school, would be dealt with by firmer methods But Idol cannot free associate for the psycho-analyst, nor does he present pants that can be kicked, so more time-honoured, if temporising, methods are used and he is promised a nice holiday in the country as soon as the fine weather comes Have human communications so corrupted his good manners that Idol seeks the secondary gain from illness and perpetuates symptoms that should be evanescent or after all were the older pathologies true that rested on separated synapses and punctiform hæmorrhages as causes of apparently hysterical symptoms? How, too, should the humble clinician classify Mr Buxton's blasted cows, whose dreamy placidity and anorexia doomed them to slaughter? It is all very confusing

* * *

All morning I was behind schedule Various foreigners (by which we mean all those unfortunates who have not lived in this neighbourhood for at least 10 years) strolled late into the surgery for long consultations explaining cheerfully that they thought surgery hour was from 9 30 to 10 30 instead of from 9 to 10 The result was that I started late on my long morning round knowing that I had to be back at all costs for a series of appointments starting punctually at 2 30 P M On these occasions I refuse to look at my watch, for if I do I get fussed, but I am not above taking a sidelong glance at the clocks in patients' houses, always fondly hoping that they may be fast Still with several visits to do and wondering just how late I was I reached a house about 6 miles from home There was no clock on view as I proceeded upstairs to my patient's bedroom Downstairs, six "pips" sounded The one o'clock time signal No lunch today,

In England Now

A Running Commentary by Peripatetic Correspondents

I'VE just read General Wavell's articles in the *Times* on the art of generalship It struck me that the application of the principles which he enunciated was far wider than he claimed, in fact that they held good for leadership in all walks of life To make it clearer in my own mind I sat down with pencil and paper and wrote out his "qualities necessary for a general," arranged roughly in order of importance The result was like this —

1 *Toughness*—Robustness, even solidity, ability to stand up to shocks, mental toughness more important than physical

2 *Courage*—Determination, energy, the fighting spirit, the will to win, the spirit of adventure "a touch of the gambler"

3 *Common sense*—An ability to see what is and what is not practical or possible

4 *Administrative ability*—An ability to devolve responsibility, and to suit instructions to the capacity of one's subordinate

5 *Natural qualities of leadership*—Interest in, and knowledge of, humanity, the capacity to inspire the confidence respect and appreciation of one's men, rather than their affection, firmness combined with justice, a position which is remote but not aloof, appreciation of humour, but little demonstration of it

6 *Clarity of purpose*

7 *Imagination*—Adaptability, craftiness

8 *Observation*

With this as a basis, I constructed what ought to be called "the Wavell Psycho-biogram" You take any person you like and mark him or her from 0 to 3 under each of these headings 0 means complete "absence of the quality", 1 means "quality present but not up to general standard", 2 means "present up to general standard", and 3 means "maximal amount present" (Cæsar or Napoleon class) Maximal marks are 24, pass marks for a general or other leader position are 16, below that, "ploughed" Before I marked my subjects, I classified them as leaders or non-leaders, so as to test out whether theory and practice went hand in hand Here is my table —

Subject No	I	II	III	IV	V	VI	VII	VIII
Leader	Yes	Yes	Yes	No	No	Yes	No	Yes
Quality								
1	2	1	2	1	2	3	2	2
2	2	2	2	3	2	2	1	2
3	3	2	2	1	2	2	2	2
4	2	3	3	1	2	2	1	2
5	2	3	2	1	1	3	1	3
6	2	2	3	2	1	1	1	3
7	2	2	2	2	1	2	2	1
8	2	2	2	2	3	3	2	2
Total	17	17	18	13	14	18	12	17

So it seems to work all right All my subjects were outstanding people in their own line I was a physiologist, II a schoolmaster, III a doctor, IV a social scientist, V an artist, VI an administrator, VII an engineer, and VIII a matron, IV, VI, and VIII were women One day Wavell psycho-biograms may form an integral part of the work of army selection boards Until we reach that enlightened age, however, I can strongly recommend them as a fire-side game for whiling away the blackout

* * *

When I was a boy some aunt or other well-meaning person gave my brother for Xmas a little book called "Parables from Nature" I don't think any of us ever read it, it was considered the very essence of slop, and it became a family joke to secrete it among one of the others' luggage, especially when going back to school Later when any of us went abroad it invariably found its way into his or her belongings, and I have been rendered suddenly, poignantly and hilariously homesick in mid-Pacific and in the Indian Ocean by coming across that little cream-coloured volume of Mrs Gatty's, skilfully hidden in my whites "Parables from Nature" must be one of the most travelled volumes in existence Yet, when some weeks ago, Jan 12 to be exact, I found glowing under a cowl of snow the radiant blossom of a winter aconite, and another one coming up, breech presentation, beside it, I felt impelled to write a parable from nature myself For how does this little gem manage to extract nourishment and energy out of the frozen ground? The answer is, of course, it doesn't, it did all that last spring and summer, and stored it up in its nobbly corm Thus and no otherwise should all those on whom the warring nation counts store up for themselves energy and health during the coming spring, summer and autumn Cabinet ministers should don the shortest of shorts and run and bask on the Terrace, the majority of the Services will get plenty of sun and exercise in following their avocations, but munition workers, especially those youngsters who are just going into industry, should, if in any way possible, have their summer camp, or at any rate a series of week-end camps Last year my own camp which normally takes about 600 boys each season did not have one, 600 fortnights of health storing lost, and that was going on all over the country It will be unscientific folly of the worst kind if hiking and biking and camping are given up They should be encouraged, even to the edge of compulsion For consider the aconite, and remember that next winter may be the testing time of staying power

Some weeks ago the upheaval of war brought a contemporary student at my old hospital and me together for a fortnight of close contact During the 5 years we had been fellow students, as far as we could remember, we had never spoken to each other, in my mind was a dim memory of a slim figure with books under his arm, knowledgeable beyond the dreams of decency, who because he did not play games hardly intruded within my myopic range, his memory was of a rather noisy individual, definitely of the unintelligentsia Of the 25 years since then he has been a psycho-analyst for 12, and for 4 years before that he was analysed himself, while for most of that time I have been scudding about the earth's surface more or less on my lawful occasion. We swopped yarns I told him of my mild adventures in the Pacific, of that sorceress of cities, Istanbul, of treks in Australia, of China seas, only touching up the truth when it seemed irrelevant or disappointing He beat me every time, he'd been much further afield He told of a strange land where someone called Id held sway, where people went about seeking incestuous connexion with their parents or alternatively longing to murder them, of a strange sect that fell down and worshipped an old god, Fundament, of another country insecurely held by a supercilious dictator called Super ego, of complex plots and stratagems, conducted in a weird and cabbalistic language, of horrid doings when this ruler slept, of taboos and castrations In the last fortnight we have made up a good deal for our 5 years silence, especially at meals, but I think the consumption of salt on both sides has been abnormal

* * *

Motives for joining the services, I have learnt, vary from unalloyed patriotism to frank self interest Orphaned by the last war and Irish by birth I abound in neither military virtues nor in patriotic sentiment for an English government, but the break through in France with Dunkirk and the first threat of invasion provided a sufficient stimulus for me to enter my name when I reached the end of a house-physician's appointment in London, and within a few weeks I was commissioned in the R A F V R July found me attending the ten days' course which converts civilian practitioners into service medical officers During this time I listened with amusement to the squadron-leader detailed to instruct us in "service customs" and marvelled at the punctilio with which, judging from their supplementary questions, some of my companions proposed to conform, I listened at first with boredom but later with infectious enthusiasm to the officer who instructed us in the ways of making latrines so that no fly could get in, or, if it did, neither it nor its burrowing progeny could possibly find a way out, I listened with satisfaction to a discourse which reduced the prevention and treatment of venereal disease to the simplest proportions, I tried to sleep through

Letters to the Editor

REATMENT OF HYPERTOXIC DIPHTHERIA

IR,—I read with much interest the papers by eara and McSweeney and your leading article of 15 The belief of the Dublin workers that the htheria bacillus in the body produces two factors nd B, and that the ordinary commercial serum, while ctive against A, is relatively unsuccessful against B, ourages me to give my experience in the treatment of ertoxic cases of diphtheria with commercial serum s a blood-transfusion from a suitable adult donor treatment is based on the theory that the average lt is immune to the type of diphtheria prevalent in district The adult's blood contains antibodies ich are specific for the *disease* and not just for one tor of it Certain antibodies are present which are available in very small quantities in commercial itoxin A combination of commercial antitoxin plus antibodies present in a suitable local adult's blood uld contain all the antibodies required for treatment a local patient A transfusion from such an adult uld also benefit the patient by adding healthy blood his own and diluting the circulating toxin The very ere cases are given 60 000 units of commercial antin intramuscularly and a similar quantity intraously The blood for the transfusion is preferably en from the pooled blood of many donors rather than This blood can be got by arrangement from a local od bank It is advisable to dissect down on the vein l tie in a cannula The blood is not heated and is en by the drip method The average quantity ected is a pint, but this depends on age and so on e results are very satisfactory and an improvement is ted very quickly in the patient The cases so far ated have shown none of the complications usually ociated with the hypertoxic type of diphtheria I gest that, since the serum mentioned in O'Meara's d McSweeney's articles is not yet available commercily, ordinary commercial antitoxin and a transfusion of ole blood be used instead

ublic Health Dept, Gorseinon Swansea **G E DONOVAN**

POST-WAR HOSPITAL POLICY

SIR,—Mr Somerville Hastings writes with much voted experience and sincerity, but attention should drawn to the concluding paragraph of his letter where says "It is the people of this country who use hospitals It is the people who must control them, ough their national and local representatives" Does mean local authorities, elected often on a 30 per cent ll for many qualities and policies, mostly far removed m hospital experience? Or does he mean Parliament, cted on a party vote which has little or nothing to with hospitals? My own experience, as a county O H for 16 years and as M P for 21, urges me to omit that such a suggestion means hospital management a bureaucracy, however able and honest, but little resentative of the people, and that what the people nt is hospitals and staff that have their confidence, ially as a result of long tradition and self-sacrificing rk of those who run them and support them

This is the hospital problem before us, not to be met any cut-and-dried system of mere municipalism or luntaryism, but by a wise combination of the best alities of both systems

Hatfield **FRANCIS FREMANTLE**

TREATMENT OF WAR NEUROSIS

SIR,—It seems to me that the revival of the old conversy left over from the last war between the "getm-fit-quick" and the "slow-but-sure" schools, may left to settle itself in practice, since it all depends on type of personality, the type of neurotic reaction, l the time at which the case receives efficient treatnt, not to mention the kind of therapist

Dr Slater and his colleagues stressed the importance facing the problem of "boarding category" as soon possible, and of re-adapting the neurotic soldier for entry into a useful civilian life My experience has en mainly with soldiers discharged from army life neurosis, after having had or more often not had, suitable treatment They are certainly not re-adapted, and have managed to come in the way of further psychological treatment more by luck than good management Surely, here is a question that should be tackled at once, before we have an army of civilian neurotics clamouring for pensions Is there any reason (except the spurious one of saving money) why these men should not be kept on at E M S hospitals, as civilians, until as much as is possible has been done for them, instead of being hustled out into a difficult world soon after being boarded?

There is a golden opportunity not only now but after the war, to procure for cases of neurosis suitable residential treatment, which has never before been possible It will only be by lack of vision that this will be lost, and we shall once more be left with recrimination and muddle

Birmingham **CHARLES BURNS**

CHEMOTHERAPY OF CEREBROSPINAL FEVER

SIR—Dr P H Willcox and Dr G Cutts criticise (*Lancet*, Feb 8, p 191) my dosage of 9 g daily of the sulphonamide drugs in cerebrospinal fever during the initial period of 2–3 days They have apparently had complete success with 6 g daily of sulphapyridine in the few cases which they have treated This I can believe, but suggest that a larger experience of this dosage will occasionally lead to disappointment They state that I "consider that two days' treatment with sulphapyridine should be enough to eradicate the disease" They will find no such assertion in my paper, explicit or implied Perhaps they refer to my statement that meningococci were never found in the cerebrospinal fluid after 2½ days of sulphathiazole in standard dosage (9 g daily for an adult) From my earlier papers they will see that in 1938–39 29 out of 30 bacteriologically verified cases treated with this dosage of sulphanilamide had the cerebrospinal fluid free from organisms within 48 hours, and the same was true of 33 out of 34 cases treated with sulphapyridine In the epidemic period of 1940, out of 120 cases (80% bacteriologically verified) apparent sterilisation of the fluid was delayed beyond 48 hours in only 1% But no-one should infer that the disease has at that stage been eradicated, or limit the duration of chemotherapy in this disease to two days It is obvious that the more rapidly the C S F is sterilised the less will be the liability to relapses and sequelæ, and the more certain the cure I have seen several cases in which the lower dosage did not render the C S F free from organisms so rapidly, and indeed, with sulphanilamide, led to apparent drug fastness of the organism In infants I have seen and been informed of a considerable number of avoidable deaths where a low initial dosage of sulphapyridine (1 g daily) was used Why take the risk with the lower dosage when the higher has been proved to be not only effective but safe?

In view of the low case-fatality which I recorded in my series, Dr J M Kennedy (*Lancet*, Feb 15, p 231) asks for an explanation of the Registrar-General's weekly returns for London which, in 1940, showed 868 notifications and 158 deaths (fatality 18%) In contrast with this I had 234 verified cases treated during 1940 with 14 verified deaths (fatality 6%) If my cases are excluded from the London figures, the apparent fatality for the rest of London would appear to be considerably higher than 18% I raised the same point in connexion with the statistics for the first quarter at a meeting of the Royal Society of Medicine in May, 1940 I was informed that these notifications and deaths did not necessarily refer to the same people, since, for example, cases might be treated in London hospitals which were notified elsewhere, and further that the figures were subject to correction in respect of altered diagnosis It would probably be fallacious to consider the Registrar-General's weekly returns in the London district as anything more than a rough guide to the true fatality-rate of cerebrospinal fever In this connexion I was puzzled by Dr Kennedy's statement that the weekly returns showed 235 notifications for Sheffield (with 46 deaths) and that he treated 235 Sheffield cases in his hospital Does this mean that in no case was the diagnosis altered after admission to hospital? In 1940, 17% of cases certified as cerebrospinal fever on admission to this hospital had the diagnosis corrected, and a much smaller proportion admitted as pneumonia, enteritis, &c were found to be

I thought, and groaned inwardly Outwardly dissembling, however, as best I might, I listened to my patient's troubles and began to examine him Downstairs another six "pips" went off H'm, rather surprising You don't usually get two time-signals at a few minutes' interval like that Odd What was odder was that neither time-signal had been followed by the low, muttering delirium of the announcer reading the news I finished my consultation, took leave of my patient and turned to go downstairs Curiouser and curiouser—another time-signal Could the BBC have gone off its respectable rocker or the Narzees be monkeying about with our sacred G M T ? I could make nothing of it Stepping into the drawing-room to discuss the patient's case with his wife I noted to my relief that it was only 12.15 by the clock which, I was assured, was right Incidentally the mystery of the time-signals was solved People ought not to keep parrots in places where they can hear the wireless

MEDICINE AND THE LAW

Unjustifiable Deduction by Insurance Committee

THE success of Dr H Tudor Edmunds of Slough in suing the Bucks Insurance Committee raises a point of general interest to the profession He had formerly treated a patient who is the manager of a firm trading as Scott and Bowne The firm had been "evacuated" to a place about 3½ miles from the doctor's own home and outside the district in which he usually practised A year ago the manager, aware of his skill, asked him by telephone to come and see two women employees of the firm who were ill He attended them and, two days later, also attended another woman employed there Dr Tudor Edmunds entered the attendances in his day-book as one item debited to Messrs Scott and Bowne Nothing was said at the time about their being insured persons *He made the visits at the request of the manager* He sent in his account to the firm for £4 0s 6d , when asked to give particulars of the amount charged in respect of each of the three patients, inasmuch as two of them were insured persons, he did so The case of the two insured patients was afterwards taken up by the firm with the insurance committee Dr Edmunds is himself on the list of insurance practitioners for the county of Bucks and has some 900 panel patients The insurance committee, without hearing his side of the matter, deducted £3 13s (in respect of his charges for the two insured patients) from the money otherwise admittedly due to him Having in effect been fined £3 13s, he claimed this sum in the Windsor County Court on Feb 4

His Honour Judge Cotes-Preedy had no doubt that the manager of Messrs Scott and Bowne had asked Dr Tudor Edmunds to go and exercise his medical skill , he exercised it, and nothing was said about any patient being on the panel until some weeks later The contract was not between the doctor and the insurance committee but between the doctor and the patients' firm The insured persons did not pay the fee , the insured persons, therefore, could not recover the money or ask the insurance committee to refund it The deduction could not be made under the regulations The court gave judgment for the plaintiff with costs on the highest scale, the case being considered as one of importance to the medical profession and to insurance bodies

Dr Edmunds, whose claim was undertaken by the Medical Defence Union, has vindicated a point of principle He visited the firm's employees as a private doctor, not as a panel doctor Had he known that they were panel patients, he would doubtless have given them the name of another practitioner in that district Doctors are often called in by firms to deal with employees in similar circumstances because it is found more convenient to have the services of one practitioner than a dozen The Bucks insurance committee contended at one point that, as it was a semi-judicial body, the judge had no jurisdiction in the case, the matter being covered by the medical benefit regulations His Honour drily observed that, if the defendant committee set itself up to be a judicial body, its conduct was singularly unjudicial *Audi alteram partem*, indeed, is a fundamental rule of natural justice Recent examinations of the functions of administrative tribunals have repeatedly emphasised that a man must not be condemned unheard This is an ancient principle As a judge quaintly remarked in a bygone century, God did not even expel Adam from Eden without first calling upon him for an explanation

Appeal of Pharmacist against Erasure

The first appeal from a decision of the statutory committee of the Pharmaceutical Society in accordance with the provision of the Pharmacy and Poisons Act, 1933, was heard on Feb 13 and 14 by a King's Bench divisional court consisting of the Lord Chief Justice (Viscount Caldecote), and Mr Justice Humphreys The appeal was brought by Mr Barry Lawson, whose name the statutory committee had directed should be removed from the register of pharmacists (THE LANCET, May 11, 1940, p 907) on the grounds that he had been guilty of misconduct in distributing to the public by post and without invitation or request a printed pamphlet of an objectionable or indecent nature The pamphlet advertised drugs which were described as "Hormonal treatment for impotence and nervous debility in men and frigidity and apathy in women" The court decided to dismiss the appeal, the Lord Chief Justice observing that there were some parts of the pamphlet that appeared to go so far beyond a mere medical or scientific advertisement that it was not surprising that somebody thought it should be made the subject of a complaint to the Pharmaceutical Society Mr Justice Humphreys observed that the pamphlet "has not the remotest claim to be considered a medical advertisement It is a mere catch-penny document designed to induce unwary persons to pay most preposterous prices for the drugs which are there advertised" The decision of the High Court is interesting in that the action of the statutory committee which it upheld was the first occasion on which disciplinary action had been taken against a pharmacist contravening the provisions in the "Statement upon matters of professional conduct" which was issued by the council of the Pharmaceutical Society in April, 1939 The statement was issued for the guidance of pharmacists and corporate bodies carrying on business under the Pharmacy Acts and one of its recommendations was that advertisements of medicines should not be issued to the public referring to sexual weakness The Pharmacy and Poisons Act, 1933, provides that the names of persons whose appeal to the High Court has been dismissed may not be restored to the register by the statutory committee except with the approval of the Privy Council

---

SUPPLEMENT TO THE U S DISPENSATORY

FOR the first time in its 107 years' history the United States Dispensatory possesses a supplement, and a very useful one it is The supplement to the 22nd edition (London J B Lippincott Company Pp 76 5s) supplies notes on all the new drugs and preparations included in the two supplements to the U S P XI and the First Addendum to the British Pharmacopœia, 193 There are monographs on ascorbic, mandelic and nicotinic acids , adrenergic drugs, including epinine, amphetamine (benzedrine) and veritol , azochloramide, heparin, magnesium trisilicate, mecholyl, stilbœstrol soluble pentobarbital, pentothal and vitamins E, K, and P Riboflavin (B_2) and adermin (B_6) are discussed in addition to thiamine hydrochloride (B_1), but aneurine hydrochloride, the name used in the Third Add to the B P 1932, is unfortunately omitted from the list of synonyms for vitamin B_1 Sulphanilamide and its congeners, sulphapyridine and sulphathiazole, receive attention, and the supplement says that sulphapyridine "is generally regarded as inferior to sulphanilamide in streptococcus and meningococcus infections, but it is the universal consensus among those who have employed it that it is superior in the treatment of pneumonia How many practitioners in this country realise this in how many cases could sulphanilamide be prescribed instead of the more costly sulphapyridine? Too think that sulphapyridine is more effective than s anilamide in the treatment of *all* infections uitful field for investigation Fortunately we m fail to restore adequate elasticity without having sort to operation, though often enough it means hard and always involves the cooperation of the patient

JAMES MENNELL

gent's Park, N W 1

POLYRADICULITIS

R,—I was much interested in Dr H S Barber's unt (*Lancet*, Nov 2, 1940, p 548) of seven cases of e polyradiculoneuritis seen by him in East Anglia ng the winter 1939–40 Similar cases had been rved by me in Sunderland at about the same period are still occurring, all have been sent in either as theria or as throats requiring hospital treatment symptoms observed by me fit in with the typical rome discussed by Dr Barber and I have no doubt such cases were widespread For the last two s or so there have been many cases admitted to ital as diphtheria which were not diphtheria and had made me wonder whether diphtheria is as alent as the notifications suggest Many of my cases of tonsillitis, of mixed infection, and of course they not be avoided by immunisation against diphtheria rected figures from the larger hospitals might be aling The increase of throat affections is to my d due in great part to the blackout and congregation helters

EUSTACE THORP

ospital for Infectious Diseases, Sunderland

PREVENTION OF DIABETES

IR,—For several weeks a discussion on this subject been going on in your columns and I can no longer ain from a few candid remarks After all, carbo- drate metabolism is such a complicated subject that agreements are inevitable and a desirable sign of lth and progress in ideas The main point under cussion is whether high carbohydrate diets place a ain on the pancreas (Best et al and Young) or prevent betes (Himsworth) Experimental work shows that partially pancreatectomised animals (Allen) and in uitary-diabetic animals (Young, Best and others) rbohydrate food "strains the islets" and produces betes, and I am certain that continuous hypergly- mia usually makes human diabetes worse Himsworth lieves that high carbohydrate diet in normal animals and en not only does not strain the pancreas but prevents e onset of diabetes, but normals have such an insulin serve that hyperglycæmia is never produced and I do t see how their reactions are directly pertinent to an gument on diabetes As far as I know a fundamental periment has not been carried out I should like to see rmal dogs transfused for 1–2 weeks with sufficient ucose to maintain a constant hyperglycæmia Whether us per se does or does not reduce pancreatic insulin d produce β-cell changes is an experiment which ould clarify the problem under discussion

Professor Himsworth admits in his letter of Feb 1 that in diabetic animals whose disease is not con- olled by insulin excessive amounts of carbohydrate robably exhaust the remaining insulin-producing ssue" (the word "excessive," to mean anything ngible, requires definition) Now I personally have rely been able with insulin to "control" human abetes in the full sense of making the metabolism and lood-sugar normal, and so think that most of my cases nd probably his) can be made worse by excess of rbohydrate For this and other reasons I have seldom sed really high carbohydrate diets, except in total abetics who cannot be made worse I feel that Professor imsworth's advocacy of high carbohydrate diets which I think has had a most beneficial effect on the eatment of absolute diabetics in this country) is no nger on such clear theoretical grounds as before and quires clarification, so too does his position on insulin kinase" from the liver This is still mentioned, nd discussed, and, if he no longer believes in it, a efinite statement would be welcome

Professor Best and his colleagues (*New Engl J Med* 940, 225, 611) make the tentative suggestion that hildren suspected as likely to develop diabetes from their eredity, and presumably also from showing slight yperglycæmia, should be subjected to preventive treat- ent consisting of low C diets and small prophylactic doses of insulin Professor Himsworth objects to this as likely (low C diets) to produce diabetes but I protest on other grounds In the first place I think the hereditary theory they quote (Pincus and White, *Amer J med Sci* 1933, 186, 1) quite unproven In the second place the life of the children under such experimental observation would be really appalling—a distressingly abnormal diet and the certainty of hypoglycæmia from the smallest doses of insulin The hypothetical prevention (and there is no possible control in such an experiment) would be worse than having diabetes itself, where, in children, a reasonably normal diet is always prescribed as a necessity I hardly feel the suggestion can be taken seriously and do not think "the goal justifies the endeavour" Dogs, yes children, no

Diabetic Clinic, King's College Hospital

Parliament

Making the best of our Rations

FROM the medical point of view the House of Lords has been the chief centre of interest during the past week Viscount BLEDISLOE, an authority on agriculture, asked the Government if they were satisfied that during the current year there would be enough essential foods to provide for our civilian population, our fighting forces, and our (indispensable) farm animals, and whether there were any particular foodstuffs increased production of which in this country was both desirable and practicable The country, said Lord Bledisloe, ought to be told what foods were essential for health and nutrition, and to what extent enemy action would prevent supplies of them coming from overseas —Lord DAWSON of PENN reminded their lordships that this was the first totalitarian war, and as civilians were contributing a larger measure to the fighting than on previous occasions a nearer equation was necessary between food granted to the forces and to those in civil life In the light of the evidence which he regarded as overwhelming, that surplus food in the Army was being wasted he pleaded for a review of army rations Viewing the matter broadly, however, he thought that the nation had suffered precious little dislocation of its life under the system of rationing Up till now there was nothing to show that malnutrition had resulted, on the contrary the young, who mattered most, were in good health and colour and just as alive with energy and laughter as in times of peace On the other hand, certain sections of the adult population had suffered a reduction of weight While Lord Dawson felt that this was not a matter of immediate moment, he emphasised the need for keeping a constant watch on national nutrition from every angle, particularly since we had to set the course to prepare for another winter Notwithstanding the strong habit of meat-eating which has been inherited by the British people Lord Dawson asserted that the nation would suffer no harm from the curtailment of its meat supplies so long as it had access to certain essential foods Meat, it was true, was a valuable article of food, because it was a source of first-class protein and because it was appetising, stimulating and satisfying But the general public were gradually realising that they could keep healthy while eating much less meat than formerly Evidence of this was the fact that in the last 25 years we had come to buy 50% more milk, 64% more vegetables and 88% more fruit Lord Dawson went so far as to say that the present rationing would benefit the habits of our people after the war was over Among the essential foods to which the population should have access were wholemeal bread, milk, cheese, potatoes carrots, leaf vegetables and fruit The basic nutritional value was impossible without an adequate supply of vitamins It was known from the records in this country of rickets, beriberi and scurvy that the risk of these diseases had been removed by small quantities of vitamins That was one of the reasons why milk must be given pride of place It was the complete food, for it contained not only fats, protein and carbohydrate in assimilable quantities but also vitamins and equally essential minerals like iron, calcium and phosphorus Experiments in England with the Oslo breakfast had suffering from cerebrospinal fever In contrast with the *discrepancy* between the fatality in my hospital cases and the apparent fatality shown in weekly returns for London, Dr Kennedy shows a *similarity* between the fatality in his hospital cases (22% in 314 cases) and the apparent fatality in the weekly returns for Sheffield (19 6% in 235 cases) He suggests that, as some of my cases were first seen at, or admitted to, L C C general hospitals they form a selected group not containing the fulminating type of case, and asks how many of my *cases were sent on from general hospitals* The answer is 144 or 61%, more than two-thirds of these were transferred from the receiving room of the general hospital without being admitted to the wards, and nearly all the remainder were transferred on the morning after admission Fulminating cases were found to be readily transferable I have classified as severe, or very severe, 89 or 38% of the whole series Dr Kennedy mentions that 35 of his 70 deaths occurred within 24 hours of admission, but, similarly, in my series 6 of the 14 deaths occurred within 24 hours of admission, and 7 were from general hospitals and 7 from home Dr Kennedy also asks the number of deaths which took place at the other London hospitals before patients could be transferred This information is unobtainable at short notice but I have ascertained that the distribution of 157 registered deaths in London during 1940 were L C C fever hospitals, 64, L C C general hospitals, 50, other hospitals, 38, private addresses 5 I do not yet know the distribution of the 50 deaths among the L C C general hospitals, nor what proportion of them represent fulminating cases, nor the total number of cases admitted to the general hospitals It is possible, however, that some of them might have raised the mortality in my series had they been admitted direct to Park Hospital

As far as I can judge, there are other factors concerned in my low fatality-rates One is the verification of all deaths post mortem by a pathologist No less than 16 deaths in cases admitted as cerebrospinal fever were due to tuberculous or Pfeiffer meningitis, cerebral abscess, tumour, hæmorrhage or ulcerative endocarditis Diagnosis altered in the P M room does not always appear in the death certificate In this way, probably 16 deaths instead of the true figure of 14 appeared in the Registrar-General's returns in respect of my series

Apart from the question of dosage, the following factors are, in my opinion, important in treatment and should be applied immediately on admission, since delay may be fatal intravenous sulphapyridine or sulphathiazole in every severe acute case, tube-feeding in comatose cases night and day in the first 48 hours if necessary, parenteral fluid if there is much vomiting or dehydration, the general use of sulphathiazole in preference to sulphapyridine because it rarely causes vomiting and dehydration, and may, besides, be a more potent drug All this means that experienced medical and nursing assistance must be available for every case admitted even at such awkward times as the middle of the night, Saturday afternoons, Sundays and bank holidays That is why, in my opinion, the treatment of cerebrospinal fever in an organised unit for each district is likely to yield the best results

Park Hospital H STANLEY BANKS

SIR,—I was glad to see the letter of Dr Willcox and Dr Cutts in your issue of Feb 8 dealing with Dr Banks's remarks on the dosage of sulphapyridine in cerebrospinal fever Indeed, before I read it I had a letter prepared for you pointing out the false deduction as to the cause of the relapse in Dr Banks's case 1 May it not be that the improvement in his cases after transfer to the Park Hospital was due to factors other than increased dosage? We have had similar experiences with the lower dosage Adequate fluid intake, for example, is one of the most important factors in successful treatment and this is probably achieved most successfully in a good infectious-diseases hospital The numbers in Hastings have been small, but have included some very severe cases, and, although we have noted the unsatisfactory results of low dosage, we have had reason to be satisfied with the "pneumonia dosage" of sulphapyridine, supplemented in a few cases by 1 g of the sodium salt intramuscularly on the first day Since the introduction of sulphapyridine, 22 cases have been treated with no fatality or permanent complication except a doubtful cardiac lesion in an airman who however, was later passed for full flying duties We are therefore disinclined to increase our dosage without good reason and would welcome further discussion of the subject Dr Kennedy's letter of Feb 15, quoting a mortality of 22% in 235 Sheffield cases, treated by dosage even higher than that recommended by Dr *Banks, gives further ground for reviewing this* subject In connexion with Dr Kennedy's final point, I would add that the 22 cases referred to in this letter include all the cases (18) notified within the borough, 4 cases were admitted from surrounding areas

Health Department, Hastings K J GRANT

HIGH BLOOD-PRESSURE

SIR,—I have just read three articles on high blood pressure which doubtless summarise the latest knowledge we possess In 1912—quite frankly, to my surprise—I was fortunate enough to be awarded the medal of the Hunterian Society for my essay on this subject After having read these articles I looked up the original essay I had forgotten much of what it contained To my surprise I found that the articles contained practically nothing more than I had written 30 years ago Regarding ætiology, management of a case, apparatus and treatment I found nothing new except mention of the xanthine derivatives In a limited—a very limited—sphere these preparations have been "useful", I think this is also all one can say of them A few other drugs and forms of treatment, not known in 1912, are mentioned in the articles and are almost all turned down as having given "disappointing results," which is perfectly true It is to me, a sad reflection that a subject so important as this should have been at a standstill for so many years, this in spite of the enormous amount of literature surrounding it

Upper Harley Street, N W 1 A GRAHAM STEWART

SUPPORT FROM THE U S A

SIR,—The subjoined extract is taken from a letter written by a surgeon in the U S A on Jan 7, when the Lease-and-Lend Bill was in its infancy It indicates how widespread at that time was the desire to help Britain to the utmost

> "You—I mean England—are having enough trouble We are going to do everything to see that England doesn't fall To you it may seem slow A few months more will make a difference that even you will not believe You read of opposition but it is a small minority—but vociferous

London, W 1 ARNOLD LAWSON

CRAMP AND THE ILIO-TIBIAL BAND

SIR,—After reading your annotation of Dec 28 (p 816 I thought the following record might be of interest

A middle aged lady, who had been severely injured in motor accident, was advised to seek my advice for very so called sciatica Examination showed that the ilio band was so sore and inflamed that, with her doctor's con I told the patient that I thought the only thing to do was divide it, following Ober's technique The patient inquired what it would involve, and I replied a week in bed and then gradually getting up during the next week, that is a f in the home all told We were somewhat disconcerted the patient said that she considered the proposal quite possible, because, far from being able to stay in bed for a *she had never been able to do so for as much as two h* for the last eighteen months on account of cramp Still had nothing else to suggest and reluctantly the patient consented From the moment the band was divided the cramp entirely disappeared, and I am thankful to say it has recurred since The operation was performed over years ago

Of course, nothing can be claimed from a single and it is not the general practice to refer patients cramp as the main symptom to the physical department Knowing, however, the technique examining the elasticity of the band, and knowing the widespread *symptoms that can be attributed* to the loss of elasticity in it, it seems that this might

nd for trained medical personnel —Mr Brown replied
informed that 18 alien doctors, all of whom are citizens
J S.A, have so far been registered under an order of
ber, 1940, which applies only to such citizens and to
ns I am not aware that any of this group of doctors
the fighting services Under a more comprehensive
f January, 1941, the cases of some hundreds of alien
, who are of allied nationality or refugees from enemy
es, are being investigated as speedily as possible, but
ve yet been registered

R W Sorensen Why are Spanish refugee doctors
en the same opportunity as other refugee doctors in
ermitted temporarily to practise in this country, and
e Minister take steps to remedy this —Mr Brown
ject of the order is to facilitate the enrolment of
e foreign doctors in such services as the armed forces
r own countries present in the United Kingdom and the
l service of this country So far as I am aware these
s would not benefit to any appreciable extent by
n to the list of territories specified in the order

Exchange of Medical Officers

T E Groves asked the Minister whether a scheme had
repared for the exchange of medical officers of hospitals
bed areas with those in less active areas, and, if so,
was the procedure —Mr Brown replied No arrange
for such exchanges have yet been found necessary, but
atter is being kept under review

edical Grading of Emergency Reserve Officers

Reginald Blair asked the Secretary of State for War
mbers of the Army Officers Emergency Reserve rejected
edical grounds were in all cases given information as to
medical grading, and, if not so informed in all cases,
l he see that the practice was now changed —Captain
R Margesson replied It is the practice to inform all
bers of the Army Officers Emergency Reserve in which
cal category they have been placed, except in amputation
for which no grading exists In the latter cases, mem-
are told whether or not they are fit for employment

ttendance of Recruits for Medical Examination

G Muff asked the Minister of Labour whether he was
e that persons had refused to attend for medical examina
after proper registration for military service, and could
tate the policy of the Government in such cases —Mr
est Bevin replied Proceedings are taken when appro
e in order to secure attendance before a medical board
e difficulty has arisen in certain cases where men have
ed to submit to a proper medical examination and I am
idering whether the law needs strengthening in this
exion

Rehabilitation of Injured Workers

r Morgan asked the Minister of Health what steps were
g taken to secure modern and adequate fracture treatment
dustrial injured workers, whether the organisation of
treatment would be on the lines recommended by the
A committee and by the Delevingne interdepartmental
mittee in approved fracture clinics in hospitals or other
res, whether appropriate steps were being taken or
ded to be taken to secure the necessary subsequent
notherapy as well as proper rehabilitation and retraining
the stage of minimum residual disability had been
hed, and whether, having regard to the need for national
omy and for the provision of similar treatment in cases of
ries in other than industrial workers, he would consider,
oöperation with the other Government departments
erned, the advisability of the immediate establishment of
mprehensive national scheme for the future treatment and
bilitation of all injured persons —Mr Brown replied
onjunction with the Minister of Labour and Secretary of
e for Scotland I am considering the better organisation of
uties for the fracture treatment, rehabilitation and, where
ssary, retraining of injured industrial workers, and will
e a further statement as soon as possible

Sickness Benefit for Fire-watchers

Ir G A Isaacs asked the Home Secretary whether
ons suffering illness caused by the carrying out of duties
heir place of employment as fire watchers from exposure to
elements or from fatigue arising from long hours without
quate rest would, as such risk was not part of the normal risk of their employment, be entitled to their wages during incapacity, or would they be covered by the provisions of the Personal Injuries (Civilian) Scheme, and what would be their position and rights under the National Health Insurance Regulations —Mr Herbert Morrison replied I am advised that a person carrying out duties as a fire watcher at premises which are business premises as defined in regulation 27A of the Defence (General) Regulations will be covered by the Personal Injuries (Civilians) Scheme in respect of any physical injury which is certified to have arisen out of and in the course of the performance of his duties In respect of such an injury sickness and disablement benefits under the National Health Insurance Acts will not be payable for the first 26 weeks and will, for any period after the first 26 weeks, be subject to the adjustments laid down in section 7 of the National Health Insurance and Contributory Pensions (Emergency Provisions) Act 1939

Advisory E H S Committee

Dr Morgan asked the Minister of Health if he would state the constitution, personnel and functions of the Advisory Emergency Hospital Service Committee, who was responsible for its formation, when it was formed and how were its members appointed, who nominated them, and how often and where had this committee met up to date —Mr Brown replied This committee consists of representatives of the Royal Colleges of Physicians, Surgeons, and Obstetricians and Gynæcologists and also of group officers, the Central Medical War Committee, the London County Council, the staffs of London voluntary hospitals, and the medical profession in the provinces, with the secretary and deputy secretary of the C M W C Its function is to advise the Minister of Health on the organisation of medical personnel in the Emergency Medical Service The committee was first appointed in October, 1939, and subsequently enlarged, by the C M W C, and was reappointed by that committee in the present month The members are nominated by the bodies they represent or directly appointed by the C M W C, as the case may be The committee has met on nine occasions at the offices of the C M W C

Grants to Universities

Mr K W M Pickthorn asked the Chancellor of the Exchequer if he could now make a statement on the Treasury grant in aid of the universities and colleges during the coming financial year —Sir Kingsley Wood replied The House will recall that, in view of the vital part played by the universities in the life of the community, the importance of maintaining as far as possible the standards of university education, and the essential contribution which the universities were making in a variety of ways towards the national effort, it was decided to maintain the provision for the current year at the same level as that in 1939—namely, £2,149,000 These considerations have lost none of their force and despite the increasing strain on the national finances, the Government, after considering a report from the University Grants Committee, have reached the conclusion that if the universities are to continue their present contribution to the national effort, the provision for 1941 must be maintained at the existing level They earnestly hope that local authorities will take similar action

Blood Donors

In reply to a question Miss F Horsbrugh said that there was no general shortage of blood donors, but that in certain areas more were needed Local campaigns were being organised in those areas

Distribution of Unrationed Commodities

Mr David Adams asked the Chancellor of the Exchequer whether, in view of the urgent necessity of preventing both inflation and malnutrition, he was cooperating with the Minister of Food in devising a scheme whereby a minimum supply of essential foodstuffs should be guaranteed to each household in the country —Sir Kingsley Wood replied The Ministry of Food is giving consideration to a general scheme for improving the distribution of unrationed commodities In the course of these considerations the Treasury among other departments concerned has been consulted and is giving the fullest possible cooperation in trying to solve the problem

---

The New Zealand minister of health has announced that the free general practitioner service, provided for in the Social Security Act, will come into force today (Saturday) demonstrated what a large part the ingredients of that breakfast—wholemeal bread, milk, butter or vitaminised margarine, cheese, salad and fruit—played in our diet, if we could have those kinds of food we might say all other things would be added unto us Lord Dawson urged the Ministry of Agriculture to take every step possible to secure greater milk production But milk was needed immediately, and to augment the liquid supply Lord Dawson advocated the importation of powdered whole milk and powdered skim milk to our full capacity He also suggested the importation of vegetable protein in the form of powder Cheese was an invaluable food and undoubtedly its present absence from our dietary was a serious loss If it could possibly be avoided he thought that our people should not be deprived both of meat and cheese at the same time He congratulated the Government on the approaching accouchement of the standard wholemeal loaf "Let our people have bread and milk and potatoes, and a moderate amount of protein food," he said in conclusion, "and I am sure that all will go well"

Lord **WOOLTON**, Minister of Food, made no attempt to hide the probability of still further food restrictions It was impossible, he said, for us, or any nation, to wage war and live to the standard to which we had grown accustomed We would have to go back to the days of simpler living The bread supplies of the country were ample and cheap, and the price was substantially unchanged from the pre-war price He had been fortified in his bread policy by much scientific advice Our greatest weakness was in the animal protein group—bacon, eggs, cheese and meat He expressed great concern about the shortage of some of those commodities, particularly cheese So long as the Mediterranean campaign went on he saw no possibility of increasing the meat ration from its present figure He had been greatly encouraged by the views on meat which Lord Dawson had given to the House Meat was not indispensable and we had potatoes and vegetables and oils We also had milk and with these things surely we could get all the energy and health that we needed So far as supplies of animal feeding stuffs were available he intended to see that they were used for the maintenance first and foremost of our dairy herds He was trying to work out a plan to secure that the available supplies of cheese went to the people who needed it in their work Months ago he had arranged for the importation of all the powdered and skimmed milk which we could get from overseas We were holding in this country powdered milk so that in an emergency milk would still be available for the public, particularly for children and those in the hospitals *He hoped that it would not be long before* something was done to reduce the demand made by the armed forces on our food-supplies

State Subsidised Food

Another debate in the House of Lords affecting national health was raised last week by Viscount **ASTOR**, who asked the Government whether they intended to develop the policy of subsidising meals, especially for pregnant women and for children, in order to improve the physique, health and mental development of the rising generation and to economise foodstuffs He pointed to the decline in the consumption of milk under the cheap milk in schools scheme from 2½ million gallons in October, 1938, to 1½ million gallons in October, 1939, and said that this serious state of affairs was likely to prejudice the welfare of a considerable number of children In about half of the local education authority areas in England and Wales no provision was made for free meals for necessitous under-nourished children and in many areas where such provision was made it was insufficient While making due allowances for the difficulties which now faced local authorities Lord Astor contended that many of them have not done as much as they could in this important matter He admitted that under the circular which came into operation last July an enormous contribution had been made to the physical welfare of children at an age when their feeding was of primary importance But he urged that the benefits of this milk scheme (by which any child up to the age of five years where the family income does not exceed 40s a week is entitled to a pint of milk a day) should be extended to include children over the age of five He also hoped that the principle which had been adopted by this milk scheme would be continued after the war was over

Lord **WOOLTON** said he had spent a great deal of his time and energy in establishing clinics and trying to persuade education authorities to provide meals and milk for necessitous slum children in Liverpool It was true, as Lord Astor had said, that the consumption of milk in schools had dropped by a million gallons, but the total increase in the consumption of milk by the population as a whole had increased by five million gallons a month Most important of all, the consumption of milk by people who were recognised as having prior necessity had risen to ten million gallons a month We were now drinking, and were likely to continue to drink, all the milk that the agricultural industry could provide Indeed, he was fearful lest the industry might be unable to provide all the milk which the people were being taught to drink The number of local authorities who were now making this provision had increased from 200 to over 250 but the President of the Board of Education was pressing on still further The Government fully recognised that now that women were being drawn into factories there would be more need for meals in schools For that and other reasons he had taken active steps to secure that there should be communal feeding centres throughout the country

QUESTION TIME

R A M C Training

Lord **DAVIES** asked the Government whether they would consider the desirability of providing units of the R A M C now stationed in country districts with facilities for practical training by arranging for them to be drafted in suitable instances to urban areas which had suffered or were likely to suffer heavy casualties as a result of enemy action in order that they might assist the first aid and hospital services in their district —Lord **CROFT**, under secretary of state for war, replied that the Government were willing to provide facilities for the training of the R A M C units in urban areas or to assist hospital services in that district where this did not interfere with unit training in military formations and the military commanders agreed that the units could be detached for the assistance of civil authorities

Allocation of Doctors

Sir **FRANCIS FREMANTLE** asked the Minister of Health what steps he proposed to take to decide the respective priority of needs of medical practitioners between those of the civil population, of local authorities and of the fighting services —Mr E **BROWN** replied The questions of priority referred to by my hon friend have already been considered by the committee on the allocation of medical man power and action is being taken on their recommendations I am considering with the other ministers concerned what organisation should be set up to deal with similar questions that may arise in future

Dr H B **MORGAN** asked the Minister whether he was aware that disquiet existed by reason of many doctors under 45 years of age being appointed to reception areas at the instance of local medical war committees or the Central *Medical War Committee*, and would he investigate the position having regard to the needs of the armed forces for doctors and to the fact that many doctors, either with greater domestic responsibilities or more advanced in years, were available for professional work in reception areas —Mr **BROWN** replied I am informed that most of the doctors transferred from vulnerable areas to reception areas at the instance of the C M W C or its local committees are over 45 years of age In any case all doctors of military age come up for consideration with a view to selection for service with the Forces The C M W C would be glad to have particulars of the doctors referred to in the last part of the question as being available for professional work in reception areas

Registration of Alien Doctors

Sir **HENRY MORRIS JONES** asked the Minister in connexion with the recent regulation permitting the temporary registration of alien doctors in this country for the purpose of medical work in the war effort, how many alien doctors had so far been granted this recognition, stating the number in the category of nationality, and how many were in the services, and whether the present machinery for facilitating this registration was working satisfactorily in view of the present urgent demand for trained medical personnel —Mr BROWN replied I am informed that 18 alien doctors, all of whom are citizens of the U S A., have so far been registered under an order of September, 1940, which applies only to such citizens and to Canadians I am not aware that any of this group of doctors are in the fighting services Under a more comprehensive order of January, 1941, the cases of some hundreds of alien doctors, who are of allied nationality or refugees from enemy countries, are being investigated as speedily as possible, but none have yet been registered

Mr R W SORENSEN Why are Spanish refugee doctors not given the same opportunity as other refugee doctors in being permitted temporarily to practise in this country, and will the Minister take steps to remedy this —Mr BROWN The object of the order is to facilitate the enrolment of [illegible] foreign doctors in such services as the armed forces [illegible] own countries present in the United Kingdom and the [illegible] service of this country So far as I am aware these [illegible] would not benefit to any appreciable extent by [illegible] to the list of territories specified in the order

Exchange of Medical Officers

Mr T E GROVES asked the Minister whether a scheme had been prepared for the exchange of medical officers of hospitals in bombed areas with those in less active areas, and, if so, what was the procedure —Mr BROWN replied No arrangements for such exchanges have yet been found necessary, but the matter is being kept under review

Medical Grading of Emergency Reserve Officers

Sir REGINALD BLAIR asked the Secretary of State for War if members of the Army Officers Emergency Reserve rejected on medical grounds were in all cases given information as to their medical grading, and, if not so informed in all cases, would he see that the practice was now changed —Captain H D R MARGESSON replied It is the practice to inform all members of the Army Officers Emergency Reserve in which medical category they have been placed, except in amputation cases for which no grading exists In the latter cases, members are told whether or not they are fit for employment

Attendance of Recruits for Medical Examination

Mr G MUFF asked the Minister of Labour whether he was aware that persons had refused to attend for medical examination after proper registration for military service, and could he state the policy of the Government in such cases —Mr ERNEST BEVIN replied Proceedings are taken when appropriate in order to secure attendance before a medical board Some difficulty has arisen in certain cases where men have refused to submit to a proper medical examination and I am considering whether the law needs strengthening in this connexion.

Rehabilitation of Injured Workers

Dr MORGAN asked the Minister of Health what steps were being taken to secure modern and adequate fracture treatment for industrial injured workers, whether the organisation of such treatment would be on the lines recommended by the B.M.A. committee and by the Delevingne interdepartmental committee in approved fracture clinics in hospitals or other centres, whether appropriate steps were being taken or intended to be taken to secure the necessary subsequent physiotherapy as well as proper rehabilitation and retraining after the stage of minimum residual disability had been reached, and whether, having regard to the need for national economy and for the provision of similar treatment in cases of injuries in other than industrial workers, he would consider, in coöperation with the other Government departments concerned, the advisability of the immediate establishment of a comprehensive national scheme for the future treatment and rehabilitation of all injured persons —Mr BROWN replied In conjunction with the Minister of Labour and Secretary of State for Scotland I am considering the better organisation of facilities for the fracture treatment, rehabilitation and, where necessary, retraining of injured industrial workers, and will make a further statement as soon as possible

Sickness Benefit for Fire-watchers

Mr G A. ISAACS asked the Home Secretary whether persons suffering illness caused by the carrying out of duties at their place of employment as fire watchers from exposure to the elements or from fatigue arising from long hours without adequate rest would, as such risk was not part of the normal risk of their employment, be entitled to their wages during incapacity, or would they be covered by the provisions of the Personal Injuries (Civilian) Scheme, and what would be their position and rights under the National Health Insurance Regulations —Mr HERBERT MORRISON replied I am advised that a person carrying out duties as a fire watcher at premises which are business premises as defined in regulation 27A of the Defence (General) Regulations will be covered by the Personal Injuries (Civilians) Scheme in respect of any physical injury which is certified to have arisen out of and in the course of the performance of his duties In respect of such an injury sickness and disablement benefits under the National Health Insurance Acts will not be payable for the first 26 weeks and will, for any period after the first 26 weeks, be subject to the adjustments laid down in section 7 of the National Health Insurance and Contributory Pensions (Emergency Provisions) Act 1939

Advisory E H S Committee

Dr MORGAN asked the Minister of Health if he would state the constitution, personnel and functions of the Advisory Emergency Hospital Service Committee, who was responsible for its formation, when it was formed and how were its members appointed, who nominated them, and how often and where had this committee met up to date —Mr BROWN replied This committee consists of representatives of the Royal Colleges of Physicians, Surgeons, and Obstetricians and Gynæcologists and also of group officers, the Central Medical War Committee, the London County Council, the staffs of London voluntary hospitals, and the medical profession in the provinces, with the secretary and deputy secretary of the C M W C Its function is to advise the Minister of Health on the organisation of medical personnel in the Emergency Medical Service The committee was first appointed in October, 1939, and subsequently enlarged, by the C M W C, and was reappointed by that committee in the present month The members are nominated by the bodies they represent or directly appointed by the C M W C, as the case may be The committee has met on nine occasions at the offices of the C M W C

Grants to Universities

Mr K W M PICKTHORN asked the Chancellor of the Exchequer if he could now make a statement on the Treasury grant in aid of the universities and colleges during the coming financial year —Sir KINGSLEY WOOD replied The House will recall that, in view of the vital part played by the universities in the life of the community, the importance of maintaining as far as possible the standards of university education, and the essential contribution which the universities were making in a variety of ways towards the national effort, it was decided to maintain the provision for the current year at the same level as that in 1939—namely, £2,149,000 These considerations have lost none of their force and despite the increasing strain on the national finances, the Government after considering a report from the University Grants Committee, have reached the conclusion that if the universities are to continue their present contribution to the national effort, the provision for 1941 must be maintained at the existing level They earnestly hope that local authorities will take similar action

Blood Donors

In reply to a question Miss F HORSBRUGH said that there was no general shortage of blood donors, but that in certain areas more were needed Local campaigns were being organised in those areas

Distribution of Unrationed Commodities

Mr DAVID ADAMS asked the Chancellor of the Exchequer whether, in view of the urgent necessity of preventing both inflation and malnutrition, he was coöperating with the Minister of Food in devising a scheme whereby a minimum supply of essential foodstuffs should be guaranteed to each household in the country —Sir KINGSLEY WOOD replied The Ministry of Food is giving consideration to a general scheme for improving the distribution of unrationed commodities In the course of these considerations the Treasury among other departments concerned has been consulted and is giving the fullest possible coöperation in trying to solve the problem

---

The New Zealand minister of health has announced that the free general-practitioner service, provided for in the Social Security Act, will come into force today (Saturday)

Obituary

JOHN McFADYEAN

KT, M B, B SC EDIN, LL D ABERD, F R C V S

Stuart London

Sir John McFadyean, who died on Feb 1 at the age of 87, did more than other any man in the past hundred years to put veterinary science on a sound footing, and it is largely due to his efforts that the standard of veterinary training has been raised from a two-year course to a five-year course with the same conditions of entry as are demanded by a university

Born and brought up on his father's farm in Wigtownshire, he had the best possible upbringing for a veterinary career, and the knowledge he then gained of the practical management of livestock and the land provided the background on which he based his essentially sound conclusions on a wide range of subjects After leaving the Ewart Institute at which he was educated, owing to the uncertainty of the outlook for agriculture he decided to adopt the veterinary profession He studied at the Edinburgh Veterinary College—now the Royal (Dick) Veterinary College—and was admitted a member of the Royal College of Veterinary Surgeons in 1876 Shortly after graduation he joined the teaching staff of the Edinburgh College as lecturer in anatomy

His dissatisfaction with the existing standards of teaching led him to study human medicine at Edinburgh University, where he graduated M B in 1882, taking his B Sc in the following year For a short time he carried on medical practice in addition to his teaching duties, but he did not find it congenial and determined to devote himself solely to his duties at the college He was always much drawn to the subjects of bacteriology and pathology, and in 1892 he accepted an appointment to teach these subjects at the Royal Veterinary College in London, later becoming the first holder of the professorship of comparative pathology there In 1894 he became principal of the college, and he held this appointment until his retirement in 1927 He set a high scientific standard in all his work and his students will remember the clarity with which the principles of bacteriology and pathology were placed before them, and the meticulous care with which all bacteriological and post-mortem examinations were carried out

In 1888, while still in Edinburgh, he had undertaken the publication of the *Journal of Comparative Pathology and Therapeutics*, whose acceptance of an article soon came to be regarded as the hall-mark of scientific accuracy Possessed of keen analytical powers, his criticisms were at times devastating, but on more than one occasion they were found to be of the greatest value in enabling scientific bodies to arrive at sound conclusions on matters of importance

Like many other workers fully occupied in research, teaching, and administration, McFadyean found little time for writing His one textbook, " The Anatomy of the Horse," has become the standard dissection guide for students and he also completed the first part on *osteology of a projected work on the comparative anatomy* of the domesticated animals

His contribution to veterinary anatomy was notable, but it is exceeded by his work on bacteriology pathology and the control of contagious disease In his evidence before the Royal Commission on Tuberculosis, he insisted that measures for the control of bovine tuberculosis were essential for the protection of the human race, and later he played a prominent part in bringing about legislative and administrative measures for the proper inspection of milk and meat For these services the Royal College of Physicians in 1933 awarded him the Weber-Parkes prize and medal His work on glanders and mallein enabled that disease to be stamped out of this c and brought under control in all the more pro countries of the world Indeed, he was a pion great development of comparative pathology taken place since the middle of the past century

His students will always remember John Mc as a great personality, distinguished of aspect and terrifying to the shy, but blessed with a keen s humour and a natural kindness which, despite discipline he maintained, won him affection and as a teacher and a scientist

In 1883 he married Mara Eleanor, daughter of Walley, principal of the Royal (Dick) Veterinary Edinburgh She died in 1929, and they leave and two daughters

SIR WILLIAM HORROCKS

THE death of William Heaton Horrocks rec many of his friends first of all the story of so surely stamped out in Malta by his A M D report of 1861 contains a treatise on the Malta by assistant surgeon J A Marston, M D, Royal Artillery, in which he described a type of ranean remittent," or " gastric remittent " fever, to carefully distinguished from typhoid In 1887 Su Major D Bruce, A M S, discovered the causative ism of the disease, isolating it from six consecutive and giving it the name *Micrococcus melitensis* T years later, Captain M Louis Hughes (killed in 1 when serving on General Buller's staff in South A in his book " Mediterranean, Malta or Undulant Fever, gave a clear account of the symptoms and signs of disease confirming Bruce's discovery of the organism In 1903 when Major Horrocks was ferred to the Royal Society commission, the germ then been recognised for sixteen years , every p measure that could be thought of had been taken to rid of it , and yet the disease continued to take its of life and health unabated The commission, under Bruce himself, investigated every means by the germ might be spread from man to man members (Horrocks, Crawford Kennedy, I E A Shaw, and others detailed for duty from time time) showed how the micrococcus escaped from human body , showed too that though it could transferred, though very rarely, to the monkey by bites of infected mosquitoes, ecto-parasitis pr played but a small part in its transmission , monkeys were easily infected, either by feeding inoculation And then, suddenly, Horrocks and reported real progress They started to examine Maltese goat, proved that it was easily infected by ing, and with the help of Captain Kennedy that a 41% of these animals agglutinated the germ , approximately 10% passed it in their milk, and these very creatures were supplying the hospitals as as the rest of the garrison ! We can recall a shown to the promotion class by the late Sir W Leishman, setting out the incidence of undulant contracted before and immediately after the stoppage goats' milk to the garrison of Malta It was one of most striking examples that could be conceived of elimination of an infection

This was, perhaps, the most valuable piece of w done by Horrocks in preventive medicine, but t were many other points on which he threw much and many problems which he helped to solve Wh assistant professor of hygiene he published his " In duction to the Bacteriological Examination of Water, for long a standard work on this subject Later published papers on varieties of intercepting traps f domestic sewage and studies on the liberation of from the bursting of bubbles and from other sources drains He demonstrated the passage of ant bacilli into the milk of a cow suffering from the dise and demonstrated the presence of bacilli in the milk a female goat artificially infected He also cal attention to the agglutination test as a means of diagnos between *Bact typhosum* and the coliform organ With Colonel Firth he edited Parkes's " Theory Practice of Hygiene," and the second edition of " Notte and Firth " For many years Horrocks was a member the Army Medical Advisory Board, chairman of th Army Hygiene Committee, and chairman of the A mittee As chief sanitary adviser to the Army he responsible for designing the "Horrocks box"—a ble contrivance for the testing and chlorine sterilition of water As chairman of the anti-gas committee played an important rôle in the elaboration of measures the defence of our troops against noxious gases was editor of the R A M C *Journal* for thirty-two s. and will be grievously missed in this capacity as as in many others by officers of his old corps

rrocks was educated at Owens College, Manchester raduated in London later, taking his M A in 1883 time he was a resident at the Brompton Hospital then transferred to the Guildford Hospital While , a chance conversation with a patient made him , of the Army, and he joined the Army Medical ce, "a step," says his daughter "which he never regretted" He married while in India in 1895, , daughter of the Rev J C Moore, of Connor co m with whom he led a life of unclouded happiness l her death in 1921 Of the two children of the riage, one, Brigadier B G Horrocks, is at present mmanding an infantry brigade His daughter was his aithful companion until his death S L C

PROF K F WENCKEBACH

Sir Arthur Keith who formed an intimate friendship with Professor Wenckebach in the opening years of this century writes Although it was as a cardiologist that Karl Wenckebach became known in the world of medicine, he is still quoted by embryologists for a research on the development of certain fish carried out when a student at Utrecht, and after he had settled to country practice in the Limburg province of Holland he came back from time to time to explain to his old professor of physiology that the irregularities of the heart observed by the professor in experimental frogs were also to be found among his patients Hence it came about that while James Mackenzie in Burnley approached the problems of the heart through the jugular pulse, Wenckebach, who was called to the chair of medicine at Groningen in 1901, studied them through the arterial pulse

From his youth Wenckebach was drawn towards our literature and our British ways of life, he was quick to perceive that the physician in Burnley represented a new power in British medicine, and a close and intimate friendship sprang up between them Both were big men—big in body, in mind and in the intensity of their interests and feelings Both had deep and burning convictions—not only concerning the misdemeanours of the heart but concerning disease in all its manifestations Mackenzie had much of the fighting Scottish convenanter in him, Wenckebach had grown up in touch with the best musical, literary and art circles of the Hague, several of his relatives had made their reputation as artists, his eldest son has become a well-known sculptor Both men—Mackenzie was Wenckebach's senior by nearly ten years—having active brains and strong tempers as well as warm hearts had reason to complain of each other from time to time, but their correspondence and friendship were never interrupted for long

Soon after I got to know Wenckebach I was investigating the relationship of visceroptosis to respiration I found he was making a similar investigation and was invited by him to Groningen to see cases in which the viscera had descended so far that the diaphragm no longer could cause descent of the abdominal viscera After days of demonstration he carried me to the coast at Harlingen, where the great professor entered into all the "fun of the fair" like a schoolboy on holiday He was an intensely lovable man—yet proud—a quality which helped to shape his strange career In 1910 the chair of medicine in Amsterdam was vacant and he was invited to fill it He informed the authorities that he would accept only if the department was reformed and re-equipped The authorities countered by appointing another and Wenckeback retaliated by accepting in 1911 an invitation from Germany to fill the chair of medicine in Strassburg In 1914, when war broke out, he was on his way to fill the chair of medicine in Vienna, His heart in these wanderings remained true to Holland It was characteristic that on resigning his chair in 1929 when he reached 65 the age he held to be the limit of effective service in a professor, he stated that he was still uncertain as to the most effective method of teaching his subject, but he was convinced that "intellectual contagion" was a first essential

Wenckebach was representative of that wonderful breed of men to be found in the Netherlands which has the gift of tongues as well as of intellect Few men born and bred in foreign countries can break through our British barrier and make us feel they are fellow countrymen Wenckebach could do this and make us laugh too, for he had a keen sense of humour We of English-speaking countries will miss him for many a year, for he was a most effective link between the English world of medicine and that which lies outside it

GEORGE HENRY MASSON

O B E, M D, D SC EDIN, F R C P E

Dr G H Masson medical officer of health for Port-of-Spain, who died recently, had done much to improve the public health of the West Indies He qualified at the University of Edinburgh in 1895, and, as befitted a student of Sir Robert Philip, as tuberculosis officer he early established a dispensary scheme in Port-of-Spain which was in advance of some English ones of that time To practical experience he added academic distinction taking his M D in 1897 and his D Sc in public health in 1907 He was elected to the fellowship of the Royal College of Physicians of Edinburgh and the Royal Society of Edinburgh He studied in Paris, Berlin and Vienna and had the gift of tongues But he wore his learning modestly and won affection as well as respect from his colleagues On the next page our account of Dr Marcano's report of the health of Port-of-Spain in 1939 suggests that the problems Masson faced in his work differed from our own only in degree

CHARLES WILLIAM CHAPMAN

M D DURH, M R C P

Dr C W Chapman, who died on Jan 31, was born in London in 1843 He qualified from Guy's Hospital in 1868 and, after being physician to the Farringdon General Dispensary in 1892 he joined the staff of the National Hospital for Diseases of the Heart Here he gave all his thought and energy in arousing the hospital from the lethargy into which it had sunk since its foundation in 1857 The Adam house in Soho Square was no longer suitable for a hospital and in 1912 the hospital was rebuilt on the site of Dr Haweis's chapel in Westmoreland Street, where it stands today Chapman was active in the selection of the site and the supervision of the building Soon after the last war he retired from the staff of the hospital, but he continued his private practice for some years and retained to the end the confidence of his patients He was always greatly interested in children and wrote a book on Heart Disease in Childhood and Youth At the age of 83 he also wrote a small handbook for students on The Heart and its Diseases, and for several years he contributed annual reviews of the literature of cardiology to the *Practitioner*

WESTMINSTER PAST AND PRESENT —The Editor of *The Broad Way*, the journal of Westminster Hospital, writes to say that four etchings of the hospital in 1734, 1834, 1934, and 1939 will appear as a free supplement in his next four issues The artist is one of the present students and the etchings are suitable for mounting and framing The first issue of *The Broad Way* containing one of these etchings will be published soon, and if any Westminster man would like to make certain of getting a complete set he should communicate with the editor

Public Health

From the Annual Reports

PORT-OF-SPAIN, TRINIDAD

For purposes of comparison with the health conditions of Britain, Dr Roderick Marcano's report of Port-of-Spain for 1939 may be taken as giving a typical picture of the health conditions in a tropical colony In 1921 the population of the city was 61,396 and the density 34 2 per acre In 1939 the population was 90,375 and density 35 6 Overcrowding, the curse of all cities, is greater in the tropics than it is here and its tendency has been to become worse Little progress was made in re-housing until quite recently, but in 1939 Port-of-Spain made some progress in this direction The population is pure " British "—that is, it is made up of all races under the sun and every conceivable combination thereof The various races which are subject to the Crown gain British citizenship but to a large extent retain their national habits and ancient metaphysics The political significance of this is enormous, but from the public-health point of view it causes great difficulties Feeding is the most important single problem confronting the health officer In Britain, where we all eat much the same foods and have much the same feeding habits, the food problem is difficult enough, but in the mixed communities of the Empire it is much more complicated Meteorological conditions in the Empire vary between all extremes of which the earth is capable, but though these influence health problems their influence is far less than was formally supposed , the general healthiness of a population is little affected by them directly, and all deleterious climatic influences are capable of suppression West Africa—the White Man's Grave of our fathers—is now as healthy for Europeans as Manchester is Strictly speaking there are no tropical diseases, but some diseases are localised because they are spread by living vectors which may have a local distribution Thus, sleeping sickness is limited to parts of Africa because it can be spread only by certain flies which have a limited distribution In Trinidad there are no diseases which might not occur in this country, but some, such as malaria, ankylostoma and a form of dengue, which here are curiosities, are there important But their influence on the health of the people is comparatively slight Of the 1503 deaths in Port-of-Spain in 1939, the number of those which would not appear on our list were 38 malaria, and 4 ankylostomiasis The only one of our diseases which does not appear on their list is scarlet fever, which for some unexplained reason is not seen, except as a curiosity, in any tropical country The vital statistics for Port-of-Spain for 1921 and 1939 differ little from those of English towns for 1891 and 1909, in fact, the health conditions of most tropical colonies are similar to those of England a generation ago, their trend is similar and their problems are similar Except that in temperate climates we do not now have to bother much over mosquito-spread diseases, or such food diseases as beriberi or endemic dropsy, health problems are identical in all parts of the world Tuberculosis, syphilis, respiratory infections and the diarrhœal diseases are the main enemies of human health and their problems are similar in kind everywhere We have taken Port-of-Spain, but had we taken Singapore on the other side of the earth, we should have been able to bring out much the same points

OLDHAM

The vital statistics of Oldham, like those of its sister towns, reflect the depression in the cotton county boroughs of the inter-war period The population reached its highest point of 148,300 in 1921, since when it steadily declined to 123,400 in 1939 Coincidentally, the birth-rate fell from 21 3 to 12 4 in 1933, rose to 13 3 in 1938 and fell again to 12 5 in 1939 The crude death-rate increased from an average of 16 4 in 1919–1928 to 17 4 in 1929–1938 and in 1939 rose further to 18 6 Corrected for transferable deaths, this shrinks to 15 7, but as the comparability factor is 1 12, the true death-rate was 17 6 compared with the rate of 12 1 for England and Wales These statistics might be those of a population losing by emigration of young adults, but the comparability factor being above unity tells us that this not so and that the loss is mainly due to loss in The infantile mortality was 60, the lowest recorded Oldham, but maternal mortality was 7 9, which exceptionally high Dr J T Chalmers Keddie's prehensive report contains a chapter on Oldham Co for Mental Health, a voluntary association affiliated the National Council for Mental Welfare, which is great interest, for Oldham council is a pioneer of a mov ment which was beginning at the end of the inter era Mental health was outside the province of hyg until quite recently and when it was taken in it found to have three formidable difficulties—it is personal , its work must be secret , and its p requires much which practitioners of medicine are not a position to deliver Its progress must therefore slow, but Oldham has made a successful start and wh is being done there is helpful

Infectious Disease in England and Wales

WEEK ENDED FEB 15

Notifications —The following cases of infectious dise were notified during the week smallpox, 0 , scarl fever, 1198 , whooping-cough, 3425 , diphtheria, 1175 enteric fever, 18 , measles (excluding rubella), 16,654 pneumonia (primary or influenzal), 2106 , puerperal pyrexia, 200 , cerebrospinal fever, 378 , poliomyelitis, 12, polio-encephalitis, 2 , encephalitis lethargica, 6 , dysentery, 174 , ophthalmia neonatorum, 62 No case of cholera, plague or typhus fever was notified during th week

The number of civilian and service sick in the Infectious Hospitals *of the London County Council on Feb 14 was 2086, including* scarlet fever, 285 , diphtheria, 322 , measles 728 , whooping cough, 190 , enteritis 23 , chicken pox, 196 , erysipelas, 58 mumps, 10 , poliomyelitis, 2 , dysentery, 8 , cerebrospinal fever, 75 , puerperal sepsis, 8 , enteric fevers 4 german measles, 2 , other diseases (non infectious), 82 , not yet diagnosed, 93

Deaths —In 126 great towns there was no death from smallpox, 2 (0) from enteric fever, 3 (0) from scarlet fever, 38 (3) from whooping-cough, 26 (5) from measles, 46 (1) from diphtheria, 36 (1) from diarrhœa and enteritis under 2 years, and 324 (50) from influenza The figures in parentheses are those for London itself

Liverpool and Yarmouth each reported one fatal case of enteric fever Liverpool had 6 deaths from diphtheria and Birmingham 5 Birmingham also had 5 fatal cases of whooping cough Deaths from influenza were scattered over ninety three great towns, Liverpool reporting 13, Blackpool 10, Newcastle on Tyne, and Bristol each 9

The number of stillbirths notified during the week was 213 (corresponding to a rate of 38 per thousand total births), including 21 in London

INCIDENCE OF INFLUENZA

In the week ended Feb 15 324 deaths were ascribed to influenza in the great towns—Feb 8, 261 (56) , Feb 1, 176 (45) , Jan 25, 120 (22) , Jan 18, 99 (17) , Jan 11, 69 (9) , Jan 4, 53 (8) The ratio of increase is thus appreciably l than between the two previous weeks The age distribu of the deaths continues to be normal In the Count London, the deaths decreased from 56 to 50 Hosp admissions in London for influenza, bronchitis and pn monia decreased from 811 to 526 and the daily records the current week show no sign of increase

---

British Drug Houses Ltd have put on the mar a jelly containing 2% gentian violet and 0 02% sodiu ethyl mercuri-thiosalicylate which they recommend the treatment of second-degree and third-degree bur particularly of the hands, feet and face Clinical tr suggests that 2% rather than the 1% gentian vio hitherto in common use may be the optimal concent *tion for burns* Gentian Violet Jelly B D H is availa in 1½ oz and 4 oz tubes

Medical News

University of Oxford

The Rockefeller Foundation have given the university [illegible] dollars for the purchase of equipment and research supplies and the provision of the salaries of assistants for Dr H W Florey in connexion with researches in general biochemistry at the Sir William Dunn school of pathology They have also made a similar grant of £1000 in connexion with research on the X ray analysis of biologically important large molecules by Mrs D M Hodgkin in the department of mineralogy and crystallography

University of Cambridge

At recent examinations the following were successful —

D.M R.E.

Part I Manfred Altmann, R. D Caton Arthur Fikeles, J E [illegible], Grace M. Griffith, Max Halberstaedter, and P C Phelps

Royal College of Obstetricians and Gynæcologists

The following have been elected to the fellowship of the college —

W C Armstrong Glasgow N L Edwards Derby A L Gunn London, Joan K. Rose Edinburgh, W A Taylor, Birmingham, and Robert Watson, Northampton

The DENTISTS REGISTER for 1941 just issued contains 15,032 names, or 22 more than last year But the total of new names (3[illegible]5) is less by 50 than in the previous year

At the section of surgery of the Royal Society of Medicine on Wednesday, March 5 at 2 30 P.M., Mr Julian Taylor and Mr R Watson-Jones will open a discussion on war injuries of the spine, and on March 7 at the section of otology at 10 30 A.M Miss D J Collier, Dr F S Cooksey, and Mr Terence Cawthorne will open a discussion on the limitations of operative treatment in facial palsy On the same day at 4 30 P.M. at the section of laryngology Mr E D D Davis will read a paper on chronic hyperplasia or focal osteitis of the maxilla

At the quarterly meeting of the directors of the Naval Medical Compassionate Fund, held on Feb 21 with Surgeon Vice Admiral Sir Percival Nicholls in the chair, the sum of £[illegible] 10s was distributed among the applicants

On Friday, March 7, at 1 45 P.M., Major General H Willans, director general of army welfare, will read a paper on that subject to the Royal Society of Arts The meeting will be held at the house of the society in John Adam Street, London, W C 2

Today, Friday, Feb 28 at 4 P.M at the University of Edinburgh Sir Joseph Barcroft, F R S, will deliver the Sharpey Schafer lecture He will speak on four phases of birth

In a recent casualty list Lieutenant J Cunningham, M.B, R.A.M C, is reported to have died

Messrs May and Baker have given a million tablets of M & B 693 to the Lord Mayor s Greek relief fund

TREATMENT OF CHILBLAINS

BY G I WATSON, M D Camb D T M & H

LIEUTENANT R A M C

PEOPLE who suffer from chilblains can be divided into two groups those who believe in calcium and those who do not The first of the following case-histories is that of a young woman who does not An observation of hers led me to use a treatment which has given her and others almost immediate relief from their chilblains

CASE 1 —A woman, aged 23, whose work includes driving and cleaning a motor car but is varied both indoors and out Two sisters suffer severely from chilblains, her mother and father have chilblains occasionally She has suffered in summer from urticaria, and blisters easily in direct sunshine She cannot remember a winter in which *she has not had* severe chilblains on both hands and on one or both feet She has been treated with calcium in large doses, both by mouth and by injection, together with vitamin D in various forms, but she has not been freed of chilblains even temporarily by such treatment One winter recently her chilblains were abolished when she stung her hand in some nettles She cannot recall whether the effect was only on the one hand or on all her chilblains

It is possible that H-substance which is closely allied to histamine is produced at the site of a sting, whether by nettles or bees I was using histamine experimentally for other purposes at the time and was familiar with its local effects after subcutaneous injection I offered with her active coöperation to inject one of her chilblains and to watch the result

On Nov 21, 1939, she was given a test dose of histamine (B.D H), 0 5 c cm, subcutaneously in the forearm, she developed a large weal with irritation round it, facial flush and frontal headache, no itching of chilblains On the 24th she was given 0 1 c cm of histamine, split into two doses, into a chilblain on the 3rd finger of her left hand, there was immediate itching but that night all itching in this chilblain ceased Next day I obtained the same result with a chilblain on her right hand, and by Dec 12, after several further injections, both hands, though scaly, were free of chilblains *Treatment of the right foot* was begun on Dec 2 and a second injection was given on Dec 12 By Dec 15 new chilblains had developed on her hands She began using bee toxin ointment (A. and H) first on her hands, and later on her feet alternated with injections of histamine At first the ointment produced itchiness without subsequent relief, but after three or four days the itching ceased and the skin became scaly as after injection Results seemed to be better if the ointment was applied after bathing in hot water, especially soft water The last injection of histamine was given on Jan 19, and on Feb 2 the calcium was stopped By Feb 9 she only experienced slight pricking in the hands and her feet were quite comfortable She continued to use the ointment locally

While these experiments were proceeding, two other patients presented themselves

CASE 2 —Male, 29, motor driver, suffering from moderately
severe chilblains on both feet On Dec 30, 1939, histamine,
0 3 c cm split into five doses, was injected into or near many [illegible] and
scattered chilblains on both feet Immediate [illegible] toxin former,
affected chilblains, not severe [illegible], with the less toxic strain given
that his chilblains h[illegible] they got good results by oral treatment with
after had been [illegible]ide and sulphapyridine, when intramuscular

CASE 3 —A[illegible] was adopted or when the actively toxigenic strain
chilblains, es[illegible]ed the results were poor and compared unfavourably
taking calc[illegible] serum, with *Cl septique* protection was only obtained
was not [illegible] sulphapyridine and then only on prophylactic adminis-
doses, [illegible]ation, and no protection was obtained from *Cl novyi*
Feet c[illegible] Singer (1940) worked with *mice and injected his cultures*
itchin[illegible] subcutaneously; treatment was oral with suspensions of
and h[illegible] prontosil, Uleron, sulphapyridine and Soluseptasine, his
beer[illegible] only clear success was with a single M.L.D of *Cl welchii*;
rep[illegible] there was a percentage survival with larger doses of *Cl welchii*
and with single doses of *Cl septique*, but the results were
, on too unequal to be convincing and no favourable results were
obtained with *Cl novyi* Henderson and Gorer (1940) used
heated spore suspensions of *Cl septique* in calcium chloride
solution and intradermal injection, in these conditions
sulphapyridine gave good protection and sulphanilamide
partial protection on oral administration up till 4 hours after
infection, results were much less convincing if injection of

spores was intramuscular or where *Cl welchii* preparations were used , the point particularly brought out in this work is that serum and sulphapyridine in the special conditions of these experiments can give results much greater than the summation of their separate effects

To summarise, the only encouraging results have been obtained in infections with small doses of some strains of *Cl welchii* when the drugs have been given before or very near the time of infection, and it is the general experience that for this purpose sulphapyridine is a more effective drug than sulphanilamide No-one has claimed better results with oral than parenteral administration, but Legroux (1940) has provided experimental evidence of the superiority of local over oral administration Jensen and others (1939) also claim that more is to be expected of local than oral administration since the former assures the presence of the drug up to the point of saturation in the vicinity of the wound, an effect which cannot be obtained with oral administration without risking grave intoxication For these reasons we have adhered in our work to parenteral administration of the drugs at the site of infection

EXPERIMENTS IN ANIMALS

Mice —A small preliminary series of investigations was made with mice which were injected with *Cl septique* subcutaneously The control of the infection was attempted with sulphanilamide and *p*-nitrobenzenesulphonamide, the drugs being administered half an hour before or immediately after infection The results are recorded in table I These experiments suggest an extremely limited degree of protection by these drugs when present from the outset of infection and a very slight superiority of the nitro compound, but nothing comparable to its superiority in vitro

TABLE I—ATTEMPTS TO CONTROL INFECTION IN MICE INJECTED WITH *CL SEPTIQUE* SUBCUTANEOUSLY DRUGS WERE INJECTED AT THE SITE OF INFECTION AND IMMEDIATELY BEFORE OR AFTER INFECTION

Infecting dose of culture (c cm)	Drug	No of mice	Result
0 5	Sulphanilamide 2–6 mg	6	All died , av time 21 hr
,,	Sulphapyridine 2–6 mg	6	All died , av time 23 hr
,,	*p* nitrobenzenesulphonamide 2–6 mg	6	All died , av time 26 hr
,,	Controls	7	All died , av time 20 hr
0 2	Sulphanilamide 1–20 mg	8	4 survived , 4 died within 36 hr
,,	*p* nitrobenzene sulphonamide 1–5 mg	8	4 survived , 2 died within 36 hr , 2 died after 36 hr
,,	Controls	8	All died , 6 before 36 hr , 2 after 36 hr
0 1	Control	1	Survived

Guineapigs —In most of the experiments guineapigs have been used, the thigh muscle of the anæsthetised animal being crushed by nipping with pressure forceps in order to reproduce conditions resembling those in which gas gangrene arises in man Twenty-four hour cultures in liver broth have been used and single lethal doses or very small multiples of the lethal dose have been administered *Cl welchii*, *Cl septique* and *Cl novyi* have been examined The results of these experiments are recorded in table II

TABLE II—ATTEMPTS TO PREVENT OR CURE INFECTION IN GUINEAPIGS INJECTED WITH *CL NOVYI*, *CL SEPTIQUE* OR *CL WELCHII* SUBCUTANEOUSLY

Injection	No of animals	Drug or antitoxin	Administration	No which died	Survival (%)	Average interval to death in days

m de = much delayed

Prophylactic (prophyl) *Administration* of drugs or antitoxin was carried out as two injections, the first 16 hr and the second ½ hr before inoculation The quantities given to each guineapig and methods of administration were as follows

M & B 693 Suspension of 0 2 g in 5 c cm of distilled water

Sulphanilamide Solution of 0 1 g in 5 c cm of distilled water (It was possible to inject a solution by dissolving with heat and injecting before the solution had cooled below body temperature)

p nitrobenzenesulphonamide Suspension of 0 05 g in 2 5 c cm "dispersol"

Curative administration —The same doses, methods and sites of administration were used in each case, but the times of administration were 4 and 7 hours after inoculation

These experiments afford no evidence that any of the three drugs used is of value in controlling an established gas gangrene infection, even when the interval before administration is very short They do, however, indicate a limited usefulness in the local administration of M & B 693 as a prophylactic agent In the last respect, however, they are distinctly inferior to specific antiserum which when given locally as a prophylactic was effective in infections with *Cl welchii* and *Cl septique* even in doses considerably less, weight for weight, than those recommended in the prophylaxis of gas gangrene in man This point, since it has an immediate practical bearing, has been further investigated in experiments in which the relative values of serum in prophylactic and curative administration have been carefully compared These observations are recorded in table III The striking contrast between the prophylactic efficiency of antiserum in *Cl septique* infection, and its failure in treatment was not observed when the virulence of the bacterium was less acutely developed—i e , when the controls survived till the second day In such experiments, of which several were made, treatment was successful, and in one of these even 50 units sufficed for cure when given four hours after infection, but in this experiment the lower limit of prophylactic protection was not reached with 1 unit

The results recorded in table III can now be considered in the light of (*a*) the recommendations made for the use of such sera in man, and (*b*) the ratio of the weight of man and guineapig They emphasise the fact that a dosage of serum equivalent to or less than that recommended for human prophylaxis is effective, whereas doses vastly greater than those recommended for treatment may be impotent within four hours of the initiation of infection They suggest that the doses likely to be effective in treatment will be at least 200–600 times greater than those effective in prophylaxis If it is legitimate to apply the findings in experiments on guineapigs to actual infection in man, it will follow that doses of antiserum 30–300 times greater than those recommended will still be ineffective in established cases of gas gangrene in man

A point which may prove of practical importance brought out in these experiments is that where you are dealing with a rapidly progressive gas gangrene infection there is an advantage in administering serum for prophylaxis in the area where the lesion exists and in which the development of such infection is expected So far as we are aware, attention has never been drawn to this point, and in fact we have failed to find in the literature any extensive observations on the relative values of the prophylactic and therapeutic uses of these sera It is, however to be noted that in the Medical Research Council s Report No 39 (1919) on anaerobic infections of war wounds, Ellis is quoted (p 130) as stating that the injection of anti-gas gangrene serum into and around the site of injury was attended with favourable results

CONCLUSIONS

From the results of experiments in mice and guineapigs, together with other work already published, it seems likely that the sulphanilamide drugs will have only a limited value in the prophylaxis of gas gangrene, and that local administration will be more useful than oral These drugs are not likely to be useful in treatment except in cases where there is a mixed infection with an aerobe susceptible to them In experimental work they are inferior to antisera in the prophylaxis of gas gangrene Antisera are so much more effective in prophylaxis than in treatment that while the former use is certainly justified it is doubtful whether the latter is It would therefore be well if the official recommendation to use antisera only for treatment and not for prophylaxis were reversed, provided waste by use on unsuitable cases was avoided There is no justification for withholding these valuable prophylactic agents from any person who is considered to be threatened with gas gangrene It is recommended that administration should take the form of multiple injections of serum into the muscles in the vicinity of the wound

PREVENTION OF PYREXIAL REACTIONS IN INTRAVENOUS THERAPY

By F A Knott, M D Lond, M R C P, D.P.H

DIRECTOR, BACTERIOLOGICAL DEPARTMENT GUY S HOSPITAL,

AND

B Leibel B Sc Med Toronto, M R C S

MEDICAL OFFICER, E.M.S, AT THE HOSPITAL

It is disappointing to find that minor pyrexial reactions still often crop up as an unexpected complication of intravenous therapy To rectify this much thought has been given to perfecting blood-storage, plasma-filtration, chemical purification and the details of apparatus, but if reactions are to be reduced to a minimum everyone—operator, supply department and nursing staff—must remember several other pyrogenic factors. Most of these are well known to be associated with contamination of distilled water and the accessory chemical solutions or imperfections in equipment or technique, but how these faults commonly arise and the quickest methods of detecting them are not so generally appreciated The present E.M S central supply service leaves the preparation of solutions and the care of apparatus as a local responsibility, for some institutions a new one These notes are made on our past and present experiences of such work.

Reactions tend to occur in small outbreaks and their notification to the laboratories is usually accompanied by requests for "sterility tests" on the apparatus and solutions used But in practice we have found failures in sterilisation extremely rare and on most occasions other faults must be sought When investigating any particular group of reactions one starts with the knowledge that trouble may arise from transfusion of any of the following (*a*) dead bacteria, (*b*) free bacterial proteins; (*c*) traces of other foreign protein; (*d*) some non-protein particulate matter; and (*e*) various materials added to the solutions from glass-ware or rubber improperly cared for or too long in use

DEAD BACTERIA AND BACTERIAL PROTEIN

It is important to note how dead bacteria or their proteins come to be found in solutions stored in sealed, unopened, screw-capped bottles We have rarely seen, when microscoping the centrifuged deposit, any dead bacteria in the finally bottled products, because the last stage of preparation includes Seitz filtration immediately before the final sterilisation But filtration does not remove free protein, and nearly two-thirds of solutions proved to have caused reactions were found to contain minute traces of protein which could probably be accounted for by previous multiplication of bacteria in them When the final filtration was deliberately omitted several of these samples showed numerous dead organisms, and by random sampling in the preparation rooms their most common source was found to be infection of the stock solutions either just after distillation and before bottling of the distilled water in bulk, or at the time of adding the chemicals to make the final solutions

When distilled water is subsequently to be used intravenously, it is essential to adopt during distillation some closed system of delivery into clean, sterilised bottles which are immediately autoclaved, capped and tightly closed Any technique which allows infected water to stand for a time warm or at room temperature before it is bottled and sterilised may permit bacteria, though they may be very few to start with, to multiply vigorously In our experience the most common contaminants acting in this way have been gram-negative bacilli of the unclassified, non-sporing, non-chromogenic type, the reactions of which do not conform to those of any defined group (such as coliforms or *Bacillus proteus*) Many of these organisms readily multiply at room temperature in distilled water, particularly if the free ammonia content be high Even with perfect protection of the stock distilled water, solutions made from it may still become pyrogenic Organisms may be added with the chemicals, especially if these are taken from large tins or bottles some time in use Again it is imperative to remove the bacteria before they have time to multiply or add soluble protein Therefore, after dissolving chemicals, rapid filtration is required with closed delivery into screw-capped bottles and immediate sterilisation by whatever method is most appropriate The filtration method we favour is the use of a Seitz-EK 14 cm disc or its equivalent, followed by passage through a sterilised sintered glass filter to remove any fibres derived from the filter disc Whatever system is adopted, it must ensure that both the distilled water and the final intravenous solutions are at all times free from bacteria either living or dead

Detection of dead bacteria in the deposit of a suspected solution is a matter of simple microscopy When present they can have a surprisingly great effect, and such solutions are in fact very dilute vaccines As a method of inducing artificial pyrexia, a small intravenous dose of a coliform vaccine is well recognised ; experimentally we have repeatedly produced the same result with vaccine made from water contaminants Admittedly the number of organisms injected needs to be decidedly higher but a pyrogenic dose may easily be given if the volume of injected fluid is large

Solutions free from bacterial bodies but suspected of containing traces of protein require chemical examination Pyrogenic samples of this type have been found to give albuminoid-ammonia figures ranging from 0 005 to 0 025 part per 100,000, whereas none was present in the water coming freshly from the still In three outbreaks it was possible to obtain evidence that infection of the solutions had taken place during preparation At the time, to confirm the usefulness of the albuminoid-ammonia estimation, samples of distilled water showing a low free-ammonia content and complete absence of albuminoid ammonia were lightly infected with bacilli obtained from other distilled water After incubation for two days they were examined after Seitz filtration Albuminoid ammonia appeared in the filtrates in amounts varying from 0 005 to 0 008 part per 100,000

OTHER FOREIGN PROTEINS

In other outbreaks, although solutions from the same batch had been supplied to all, pyrexial reactions were most common in particular wards, usually those in which the nursing staff attempted to clean, sterilise and store the delivery apparatus for themselves Gross failure in cleaning calls for no comment, but the average nurse often fails to appreciate the extreme degree of chemical cleanliness essential for intravenous work, and trouble crops up in, to them, unexpected ways For example, nearly a quarter of the outbreaks we have investigated were found to be caused by the boiling of delivery bottles and rubber tubing in the large ward sterilisers repeatedly used for dishes and instruments Often traces of steriliser water dry and leave a barely noticeable film of carbonate on the inside of both bottles and tubes Being only slightly soluble, the film may be added to at each visit to the steriliser, and although this " hardness " is not in itself pyrogenic it may hold traces of protein derived from the steriliser or from previous use of the apparatus If some of the film is rubbed off into the distilled water it will usually raise the albuminoid-ammonia figure

The same effect may be produced in another way After repeated use the inner surface of rubber tubing may become hard, rough and covered with minute cracks, especially favouring the deposit of film or retention of traces of protein In three experiments we found that if previously safe normal saline (free from albuminoid ammonia) was run slowly through such tubing during gentle twisting and compression it produced severe pyrexia when, after sterilisation, it was injected intravenously In one case the albuminoid-ammonia content rose during passage through the tube from nil to as much as 0 05 part per 100,000 Cleaning and sterilising in a ward can thus readily fall below the required standards of real chemical cleanliness Failure to deal properly with taps, drips, filters and other parts possessing " back waters " is an obvious risk, but the two unsuspected fallacies described illustrate the great care necessary The best results can be obtained only when sterilisation is done in a laboratory department where perfect cleansing and all necessary replacements and renovations can be carried out at the same time In the wards little should be done except thorough flushing with clean cold water or weak soda solution The best subsequent procedures are fully described in the M R C memorandum on wound shock [1]

A further possible source of trouble is the still itself A series of reactions took place when reconstruction of part of the hospital made necessary the temporary use of a relatively old metal still When tested, the stored distilled water from this apparatus was found to be sterile and completely free from bacterial bodies and particulate matter, but to have an albuminoid-ammonia content as high as 0 0008 to 0 001 part per 100,000 ; this, of course, had been passed on to all the intravenous solutions A large quantity of this water was therefore redistilled from glass, and the albuminoid ammonia fell to vanishing point A fresh set of intravenous solutions was then prepared from this redistilled water and issued to the wards ; no further reactions took place Several similar experiences suggest that when a water-supply is at all below the highest standards double distillation from glass should be carried out ; and should an outbreak of reactions occur one of the first tests should be estimation of the albuminoid-ammonia content of the solutions This should not be above, say, 0 0002 part per 100,000 If the figure is appreciably higher, the cause should be sought in failure to protect the solutions from bacterial contamination or in direct entry of traces of foreign protein At present the still in use for our intravenous supplies is a steam-heated, automatic Manesty No 4 model (Manesty Machines Ltd , Liverpool) and the albuminoid-ammonia content of the distilled water delivered is nil

SUSPENDED NON-PROTEIN PARTICLES

Ideal intravenous solutions should contain no trace of particulate matter An official E M S warning was issued against the chalky and other powders to be found on new rubber Particles from " perished " rubber are equally objectionable, and preliminary washing should be very thorough In some of the earliest screw-capped bottles the cap-linings deteriorated and flaked Before general adoption of the screw-cap, the cotton-wool plug was a tiresome source of fibres ; vegetable or asbestos fragments may also be derived from filters, especially if filtration is hurried But our experience has been that non-protein particles in very small numbers are less liable to cause pyrexial reactions than is generally supposed It is not uncommon for unopened bottles to be returned to the laboratory because sharp eyes have detected a few floating specks in the contents, but (except in two instances in which a mould was the cause of the trouble) tracing the rest of the batch and deliberate intravenous use of the contents of the suspected bottles has always convinced us that they had no significant pyrogenic properties All our experience suggests that traces of foreign protein in any form are far more potent in producing reactions than any of the commonly encountered non-protein particles In any case, the presence of the latter can be largely avoided by passage, after Seitz filtration, through sintered glass, and by careful cleansing and renovation of all apparatus used

---

[1] The M R C War Memorandum, No 1

SUMMARY

Pyrexial reactions complicating intravenous therapy may be due to the presence in the solutions used of dead bacteria or traces of other foreign proteins or non-protein particulate matter Foreign protein is the commonest cause

Dead bacteria or protein derivatives of them may be present as a result of faulty technique in distillation of water or sterilisation of apparatus, or of defects in outworn apparatus Solutions free from dead bacteria but containing traces of protein capable of causing pyrexia have been found to have an albuminoid-ammonia content ranging from 0 005 to 0 025 part per 100,000 This estimation is therefore useful in the detection and elimination of such contaminants

We thank Dr A H Douthwaite for giving us opportunity to test the pyrogenic properties of various solutions clinically, and Dr J H Ryffel and Mr E Hinks, B Sc, F I C, for confirmatory albuminoid ammonia estimations

OXYGEN CAPACITY OF BLOOD

AFTER SOLUBLE HEXOBARBITONE ANÆSTHESIA

By E A PASK,[1] M B Camb D A

ASSISTANT NUFFIELD DEPARTMENT OF ANÆSTHETICS OXFORD

THE occurrence of a transient dilution of the blood during the period of action of certain of the anæsthetic barbiturates has been noted on several occasions

Bourne, Bruger and Dreyer (1930) found that in dogs the corpuscular volume fell by as much as 30% during Sodium Amytal anæsthesia, but in no case did any material dilution persist for more than 5 hours after recovery Adolph and Gerbasi (1933) noticed similar changes, and Searles (1939) found that the erythrocyte count fell by some 15% but that this did not occur in splenectomised animals Dallemagne (1935, 1938), however, reported a different and more serious effect · a decrease of some 50% in the oxygen capacity of the blood in dogs after the administration of soluble hexobarbitone The oxygen capacity remained at its minimum level for at least 10–14 days, after which it slowly returned to normal The effect was accentuated when repeated doses were given, and in one animal, which received 17 mg of soluble hexobarbitone per kg of body-weight on 3 occasions at intervals of a month, the oxygen capacity fell eventually from 20 to 4 volumes % These changes Dallemagne attributed to a destruction of erythrocytes H K Beecher (1938) in a short series of intensive experiments was unable to confirm these findings In one of his experiments a dog received 30 mg of soluble hexobarbitone per kg of body-weight on 22 occasions at intervals of a week, but no evidence of anæmia was found Beecher was also unable to advance any explanation for the anæmia which occurred in Dallemagne's experiments

It seems unlikely that changes of the magnitude noticed by Dallemagne could follow soluble hexobarbitone anæsthesia in man without giving rise to clinical signs or symptoms The possibility of such changes is, however, so serious that—attention having been directed to it by several observers (e g Wynne 1940)—it seemed advisable to investigate the blood-oxygen capacity directly in a short series of patients after soluble hexobarbitone anæsthesia

The results and data concerning the patients are shown in the table Coagulation of blood samples was prevented by oxalate All estimations were duplicated, the Van Slyke manometric method being employed for cases 1–3 and the Haldane method for the remainder In none of the operations was there any considerable loss of blood In the figure the blood-oxygen capacity levels are represented graphically, in each section the central horizontal line represents the preoperative level and this figure is noted against the line The space above and below this central line represents a change of 1 volume % except in case 10, where an increase of 2 volumes % has been allowed for

TABLE SHOWING RESULTS

No	Sex and age	Premedication (gr)	Supplementary anæsthetic	Dose of SHB (g)	Operation
1	M 48	M1/6, H1/150	Cyclopropane	1	Compound fracture
2	M 17	,, ,	Cyclopropane	1, 1	Lacerated hand.
3	M 29	None	None	1	None
4	M 28	M1/6, H1/150	Nit ox and E	1	Herniotomy
5	M 58	,	Nit ox and E	2	Bilateral herniotomy
6	M 17	, ,	Nit ox and E	1	Appendicectomy
7	M 35		Nit ox	1	Removal of epididymis
8	F 59		Nit ox and E	1	Herniotomy
9	M 61	,	Nit ox	1	Fractured olecranon
10	M 58		E	1	Herniotomy
11	M 35	,	Cyclopropane	3	Bilateral herniotomy

M = morphine Nit ox = nitrous oxide E = ether
H = hyoscine SHB = soluble hexobarbitone

It will be seen that in no case did the oxygen capacity fall as much as 1 volume %

Variations in blood-oxygen capacity may be associated with such factors as sleep, feeding, emotion, sweating, and the hæmoglobin content of the blood may vary by 10–15% from hour to hour (Wintrobe 1930) The small reduction in oxygen capacity noted in some of the cases reported here cannot therefore be regarded as significant, and it may be concluded that a serious fall in blood-oxygen capacity is not a common accompaniment of clinical soluble hexobarbitone anæsthesia in man

TOXIC MANIFESTATIONS OF ANTISYPHILITIC THERAPY

FURTHER OBSERVATIONS ON CAPILLARY RESISTANCE

BY
GORDON HORNE, M R C P E
AND
HAROLD SCARBOROUGH, M B EDIN

(From the Department of Venereal Diseases and the Clinical Laboratories, Royal Infirmary, Edinburgh)

IN a previous communication (1940) we reported 1 case of toxic purpura and 9 cases of toxic erythema and dermatitis (1 showing spontaneous petechial bleeding) occurring during the course of antisyphilitic therapy with arsenic and bismuth All were found to have an associated low or decreased capillary resistance Scarborough and Stewart (1938) in demonstrating the effect of hesperidin (vitamin P) in the treatment of vascular purpura observed a decreased capillary resistance in 3 cases of purpura under similar circumstances

We report here a second series of cases investigated during the course of antisyphilitic therapy, including 9 cases of jaundice, 2 of which were associated with spontaneous petechial bleeding and 2 with erythema, and 2 cases of " vasodilator reaction " (nitritoid crisis) With the exception of 2 of the cases of jaundice, which were not considered to be clinical manifestations of intolerance, all the cases reported were associated with a low or decreased capillary resistance.

CASE-RECORDS

The capillary resistance was determined by a negative-pressure method and recorded as previously described (Horne and Scarborough 1940) The resistance is stated as the amount of suction in mm Hg required to produce a single petechial hæmorrhage in the area of skin under observation, one or more of three standard area being used, designated I, III and V

CASE 1 —Male, aged 53, with primary syphilis On March 22, 1940, three weeks after completion of the first " unit " course of treatment with arsenic and bismuth the patient reported with clinical jaundice A few spontaneous petechial hæmorrhages were observed on the limbs Fig 1 shows an associated decreased capillary resistance, which remained at this level despite clinical improvement Bismuth injections were started again on April 23 and numerous petechial hæmorrhages reappeared in association with a further fall in the capillary resistance No more injections were given, and the capillary resistance rose to a higher level

CASE 2 —Male, aged 26, with primary syphilis On April 9, 1940, during the second unit course of treatment, the patient reported with clinical jaundice The icteric index rose rapidly to 150, and gradually fell to normal Fig 2 shows an associated decreased capillary resistance, which rose as the clinical condition improved The chart also shows the occurrence of spontaneous petechial hæmorrhages during the period of low capillary resistance

CASE 3 —Male, aged 43, with primary syphilis On March 27, 1940, during the first unit course of treatment, the patient reported with erythema and clinical jaundice Previous determinations indicate that the intolerance was associated with a fall in the capillary resistance which rose as the clinical condition improved (fig 3)

CASE 4 —Male, aged 48, with secondary syphilis On July 12, 1940, during the first unit course of treatment the patient reported with an erythema No further injections were given and the erythema rapidly disappeared The patient reported with clinical jaundice on July 26 Fig 4 shows the associated decreased capillary resistance

CASE 5 —Male, age 33, with primary syphilis On June 7, 1940, three weeks after the completion of the first unit course of treatment, the patient reported with clinical jaundice The icteric index rose to 106 and had not returned to normal at the conclusion of the investigations Previous determinations indicate that the intolerance was associated with a fall in the capillary resistance (fig 5)

CASE 6 —Male, aged 28, with primary syphilis Intolerance developed during the second unit course of treatment, the patient reporting with clinical jaundice on April 2, 1940 Previous determinations indicate that the intolerance was associated with a fall in the capillary resistance which rose as the clinical conditions improved (fig 6)

CASE 7 —Male, aged 30, with latent syphilis On May 17, 1940, during the third course of treatment the patient reported with clinical jaundice Previous determinations indicate that the intolerance was associated with a fall in the capillary resistance which rose as the condition improved (fig 7)

CASE 8 —Male, aged 28, with secondary syphilis On April 30, 1940, during the second unit course of treatment the patient reported with clinical jaundice The history of prodromal gastric symptoms and chill suggested an infective rather than a toxic jaundice, and the clinical condition rapidly improved Fig 8 shows no lowering of the capillary resistance, and intravenous injections of arsenic were restarted on June 26 No intolerance developed during the remainder of the course, and the capillary resistance was maintained at a high level throughout

CASE 9 —Male, aged 26, with primary syphilis During the second unit course of treatment the patient reported on March 17, 1940, with clinical jaundice He was known to be a chronic alcoholic, and the jaundice, which was related to a bout of drinking, rapidly improved Fig 9 shows no lowering of the capillary resistance and intravenous injections of arsenic were restarted on April 9 No intolerance developed during the remainder of the course, and the capillary resistance was maintained at a high level throughout

In cases 8 and 9 the history and mildness of the attack led to the conclusion that the jaundice was not a true arsenical hepatitis, and this view was supported by the fact that resumption of treatment with the same dose of the same drug did not result in any recurrence of the jaundice, or in any other manifestation of intolerance

CASE 10 —Male, aged 31, with secondary syphilis A vasodilator reaction occurred on Feb 22, 1940, during the first unit course of treatment Fig 10 shows the associated fall in the capillary resistance No further intravenous injections of arsenic were given, and the capillary resistance returned to its original high level

CASE 11 —Male, aged 52, with latent syphilis and an allergic history A vasodilator reaction occurred immediately after an intravenous injection of arsenic on April 13, 1940 Fig 11 shows a persistently low capillary resistance

DISCUSSION

During the period January to July, 1940, 31 cases attending the male venereal diseases clinic at the Royal Infirmary, Edinburgh, who exhibited major toxic manifestations of antisyphilitic therapy were investigated Of these, 19 cases have already been reported (Horne and Scarborough 1940) and in addition 3 cases of toxic purpura previously reported by Scarborough and Stewart (1938) have received consideration, this group of 22 cases includes 4 cases of purpura (1 of which had associated jaundice and dermatitis), 9 cases of erythema and dermatitis (1 of which had associated spontaneous petechial bleeding), 7 cases of toxic jaundice (2 of which had associated spontaneous petechial bleeding, and 2 erythema), and 2 cases of vasodilator reaction The remaining 12 cases of the series of 31 have been investigated but not reported, they include 1 case of purpura, 7 cases of erythema and dermatitis (1 showing spontaneous petechial bleeding), and 4 cases of jaundice

In every case investigated we have found a low or decreased capillary resistance in association with the intolerance In addition, 2 cases are reported (bringing the whole series up to 33) in which jaundice developed during the course of antisyphilitic therapy but was not associated with any lowering of the capillary resistance In neither of these was the jaundice considered to be a toxic manifestation of antisyphilitic therapy In 10 of the 19 cases already reported determinations prior to the development of intolerance are available, and in each of them the capillary resistance has been shown to be decreased in association with the onset of intolerance

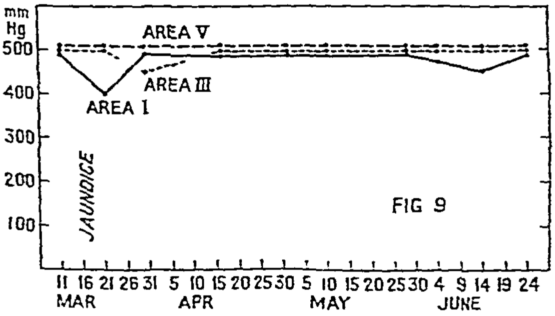

FIG 9

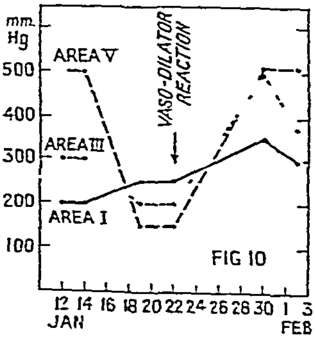

FIG 10

Ordinates are mm Hg suction.

In 5 of these cases, serial determinations are available and the onset of intolerance in each has been shown to be preceded by a falling, or persistently low, capillary resistance In 7 of the 12 cases investigated but not previously reported one or more previous determinations are available and the capillary resistance in each was found to be decreased In 3 of these serial readings show a fall preceding the onset of intolerance

CONCLUSIONS

Spontaneous petechial hæmorrhages are often associated with intolerance to antisyphilitic therapy

Toxic manifestations of antisyphilitic therapy are associated with a low or decreased capillary resistance

The lowering of the capillary resistance may precede the appearance of clinical signs and symptoms

These results suggest that the determination of capillary resistance might help to prevent the occurrence of intolerance during antisyphilitic and other forms of therapy with heavy metals

We acknowledge the facilities granted by Dr R C L Batchelor, director of the department of venereal diseases at the Royal Infirmary, Edinburgh

THE PERCUTANEOUS TUBERCULIN TEST

By F Dudley Hart, M D Edin , M R C P
MEDICAL REGISTRAR AT WESTMINSTER HOSPITAL

In 1938 I published the results of percutaneous tuberculin tests in a small series of children as compared with the intracutaneous (Mantoux) test The findings suggested that while the percutaneous method was perhaps slightly less sensitive than the intracutaneous its practical advantages outweighed its disadvantages As a result the technique was adopted of using the patch tuberculin test as a routine in children, and, if the reading was negative or doubtful, following it up with a Mantoux test 1/100 O T (1 mg) In this way the child was spared frequent intracutaneous injections, for at the most only one injection was given The Danish State Serum Institute " tuberkulinsalve " was used in most cases as this proved to be reliable and economical , the series of cases was brought prematurely to a close as the ointment is, of course, no longer procurable

Enough papers have now been published on the use of percutaneous tuberculin in children to prove that provided a strong and reliable tuberculin is used the test is an eminently satisfactory one from the point of view of both doctor and patient, particularly in contact schemes where large numbers of children of tuberculous families are tested (Monrad 1936, Wolff and Hurwitz 1937, Anzen 1935, Vollmer and Goldberger 1937, Court 1939, Pearce et al 1940) The use of a tuberculin test is essential in contact schemes and the ease with which a patch test is done makes it the method of choice in children We accordingly began to test adults and adolescents of different age-groups to find if the test was equally reliable in older age-groups Grut (1939), in the meantime, published figures in a small series of cases suggesting that although the test appeared to be less reliable in adults, comparison with the Mantoux test was favourable Of 270 Mantoux-positive adults " at most 6% " failed to react with the plaster method while in childhood only 3% failed to react Grant Taylor (1939) found the patch test slightly more sensitive than the Mantoux in young adults

SCHEME

The persons tested were all of hospital class and were all resident in or near London, though many came originally from Ireland, Scotland, Wales and elsewhere They were divided into the following groups —

1 Children aged 15 and under , 700 were tested * by three methods at the same time the Mantoux intradermal test, starting with a dilution of 1/10,000 and repeating if negative in dilutions of 1/1000 and 1/100 O T (that is, 0 01, 0 1 and 1 mg) , the Lederle (Vollmer) patch test , and the patch test using the Danish State Serum Institute's tuberkulinsalve The next 300 children received two tests only , if two tuberkulinsalve patch tests were negative a Mantoux test 1/100 (1 mg) was performed

2 Children aged 15 and under known to have a primary tuberculous focus or inactive tuberculous disease

3 Cases of quiescent pulmonary tuberculosis aged 16–50

4 Adults over the age of 59

In groups 2, 3, and 4 the tuberkulinsalve patch only was used, a second patch being applied if the first proved to be negative

5 A second group of adults over the age of 59 in whom the tuberkulinsalve test was checked by the Mantoux test

Mantoux test —Sufficient of the required dilution of O T was injected into the skin of the forearm to raise a weal 8 mm in diameter Two ink marks 8 mm apart were made with the point of a pen on the front of the forearm and the special short-bevel Mantoux needle inserted midway between To raise a standard 8 mm weal 0 1 c cm of the solution was usually necessary In this way size of weal raised and amount of O T injected were standardised as much as possible It was found that if 0 1 c cm failed to raise a standard weal some of the solution had escaped on or under the skin and the test was repeated in a fresh site The result was read in 48 hours, weal and erythema being measured and importance attached to the former A weal less than 10 mm in diameter was not accepted as positive (to be positive a weal had to be at least 2 mm greater in diameter than the original weal raised)

Lederle (Vollmer) patch test —This was used only in the first 700 cases in children and was then discarded in favour of the Danish preparation Patches were applied over front or back of the chest after cleansing the skin thoroughly with acetone and drying The patch was removed after 48 hours and read 24 hours later Positive reactions varied from a few papules or vesicles or both to a raised red area the size of the patch, with some desquamation in a few strongly positive cases

Tuberkulinsalve-patch test —The ointment is put up in 4 c cm tubes resembling small tooth-paste tubes Details of its manufacture are given by Jensen (1938) It is a mixture of purified tuberculin and old tuberculin (twice the strength of international standard tuberculin) absorbed in the ointment as a sponge, the ointment therefore having the same activity as the tuberculin itself This is as used by Monrad (1936) and is often known as the Monrad test An area of skin (free from hair) over forearm or chest was cleaned with acetone and dried , a bead of ointment the size of a split-pea was then squeezed on to a piece of ordinary adhesive tape 1 in square and the tape applied to the prepared area The amount used was reduced if a strongly positive reaction was expected One, or usually two, patches were applied, removed in 24 hours, and read after a further 48 hours Reactions were as with the Lederle test Plain squares of adhesive tape were used in most cases as controls but were abandoned in the later cases as they seemed to be unnecessary

RESULTS

A group of children under 16 years were tested by Mantoux 1/10,000 → 1/1000 → 1/100, Lederle and tuberkulinsalve-patch tests , 113 were Mantoux-positive, 587 Mantoux-negative All the negative reactions gave negative patch tests to both Lederle and tuberkulinsalve patches , 4 children who were positive to 1 mg O T intracutaneously failed to react to the tuberkulinsalve and 3 of these also failed to react to the Lederle patch , 4 failed to react to the Lederle and 3 of these failed with the tuberkulinsalve

A group of 300 children under 16 years were tested by two tuberkulinsalve patches and if negative by a 1/100 solution of O T intradermally (1 mg Mantoux) Of the

---

* This group includes the 560 cases previously reported (*Lancet* 1938, 2, 609)

247 patch negative children only 4 gave positive intradermal tests, none of them severe

Of 114 children aged 15 and under known to be "tubercularised" but without active tuberculous disease 4 (3 5%) failed to react to the Danish tuberkulinsalve-patch test

Of 170 adults aged 16–50 with quiescent pulmonary tuberculosis 18 (7 6%) failed to react to two tuberkulinsalve-patch tests

Of 70 adults aged 60 or more, 14 failed to react to the tuberkulinsalve-patch test

Of 40 adults aged 60 or more, only 1 failed to give an intradermal positive reaction (1/10,000 → 1/1000 → 1/100) This subject and 3 others (Mantoux positive) failed to react to the tuberkulinsalve-patch test

DISCUSSION

These findings suggested that the older the skin the less reliable the percutaneous test became Even so, except in the old age-group the discrepancy was not very great, though great enough to make the result of doubtful value in adults and adolescents unless controlled by a final intracutaneous test Grant Taylor (1939) made the same observation as regards the old age-group, for 12 out of his 15 non-reactors (using the Lederle patch) were over 50 years, but he found actually more patch-positive than Mantoux-positive results in young adults students, and nurses He also found the test to be reliable in coloured patients One fact that emerged from our series was that doubtfully patch-positive reactions occurred in only a few cases which proved to be negative on a second test, false positives were on the whole conspicuous by their absence

In children the test appears to be eminently satisfactory The bad reputation earned by previous percutaneous tuberculin tests was due to the insufficiently strong tuberculin used Much ground has been covered since Moro, in 1907 published the results of his inunction method, and with the strengths of tuberculin now used inunction is not necessary—the plaster is applied but no friction is used Systemic reactions do not appear to occur (though I have my doubts about 2 cases which gave strong positive reactions accompanied by a slight rise in temperature) and patients are spared the needle to a great extent The material lasts several months (10 or more) if kept in a cool place and is, if the Danish material is used inexpensive (about a penny a patch)[*] The busy tuberculosis officer with a large contact scheme can relegate the actual testing to his nurse, who asks the mother to return with the children in three days for the tests to be read Many mothers who refused to have their children "injected" raised no objection to the patch test

It was found that a recently "tubercularised" subject usually gave a strong reaction to the percutaneous test, a fact noted previously with other methods of tuberculin testing A contact, previously tuberculin-negative, gave a decided reaction to his first positive patch in several cases In a few subjects the local reaction was so severe as to cause desquamation and a degree of discomfort, but, except in the 2 doubtful cases there was no systemic reaction. The difference in skin tuberculin-sensitivity using the percutaneous test in the different age-groups is interesting The older and the more dry and inelastic the skin the more unreliable the test appeared to become, the younger and more sensitive the more reliable Nevertheless, I obtained no definite impression about "reactive" and "non-reactive" types of skin, and the failures occurred in all types from the dark-skinned Indian to the fair-skinned blonde In a few cases the test appeared somewhat later than usual—possibly they displayed the "delayed skin sensitivity" suggested by Grut

SUMMARY

Percutaneous tests were performed on nearly 1400 subjects of different age-groups It appeared that the patch test (Lederle or Danish) gave a high degree of agreement with the Mantoux test under 16 years of age and became less reliable thereafter

The Danish State Serum Institute tuberkulinsalve was adopted as the patch test of choice

Percutaneous tuberculin tests appear unreliable in old age but to what extent is uncertain In adolescents and adults the test may be of use if checked by intradermal tests when the result of two patches is negative False positives appear to be very rare

Percutaneous (patch) tuberculin tests will be found to be of greatest use in contact schemes and in excluding tuberculous disease in childhood

My thanks for help and advice are due to Dr W E Lloyd and Dr Bernard Schlesinger

ACUTE LUNG ABSCESS TREATED WITH M & B 693

By J S Richardson, M D Camb, M R C P
MAJOR R.A.M C, MEDICAL SPECIALIST AT A MILITARY HOSPITAL

SULPHANILAMIDE has not had an impressive record in the treatment of lung abscess, and Fisher and Finney[1] could find only 1 success for it out of 88 cases treated by various means Taylor, Yusuf and Chitkara,[2] however, treated 7 cases with M & B 693 with striking success in 3, all of whom had had symptoms for several weeks, 2 of the unsuccessful cases received negligible doses of the drug, but 1 admitted to hospital only three days after the onset of symptoms, died in spite of a total dosage of 40 g An annotation in THE LANCET (1940, 2, 337) pointed out that lack of success was to be expected because the presence of pus interfered with the action of sulphapyridine This suggested that the following case might be of interest

An officer in the R.A.M C, aged 26, was admitted to hospital on Oct 3, 1940 He complained of foul tasting sputum and general malaise, and had found that his temperature was raised at night His symptoms had been present for three days He had had the usual childish illnesses For some time he had had frequent attacks of tonsillitis and his tonsils were removed for this about a fortnight before his admission The operation was done under gas, oxygen and ether, with no premedication and his convalescence was uneventful until Sept 29 On the afternoon of that day he felt ill, shivering and having generalised aches Next day he went to a seaside resort still feeling unwell and two days later developed a pain in the right scapular region The following day he began to bring up blood-stained sputum which had an extremely foul taste On admission his temperature was 99° F, his pulse-rate 80 and his respirations 20 He looked ill. The condition of his fauces was satisfactory, his mouth clean and there was no fœtor His fingernails did not show any clubbing His chest showed a few crepitations at the right base and low pitched bronchial breathing at the right apex posteriorly, well out towards the upper end of the scapular spine His sputum contained small carneous lumps, slightly blood-stained, floating in a frothy mucopurulent fluid. It was not particularly putrid but the patient complained bitterly of the foulness of its taste With a view to combating this, an intravenous injection of an organic arsenical was given and the foul taste disappeared within twenty-four hours Microscopically the sputum showed neither tubercle bacilli nor Vincent's organisms, but a moderately profuse growth of *Streptococcus viridans* was grown. This was after sulphapyridine treatment had been begun A radiogram of the chest, taken on Oct 2, the day before admission, showed a thin-walled abscess at the apex of the right lung, well above the clavicle, with a fan-shaped

1 Fisher, A. M and Finney, G G *Bull. Johns Hopk Hosp* 1940, 66 263

2 Taylor G F Yusuf, M and Chitkara N L *Lancet*, 1940, 2, 320

area of pneumonitis around it The abscess cavity was about ¾ in in diameter and contained a definite fluid level On another radiogram taken on the 4th the fluid level was higher but the surrounding area of density was the same as on the previous film The patient then began treatment with M & B 693, and this was continued for three days, during which time he had 18 g by mouth The blood count taken at this time was normal in all respects, but as the patient was suffering from considerable nausea, sulphanilamide was substituted for the next few days This was well tolerated and he had 11 g of it, making a total of 29 g of these drugs On the 12th another radiogram showed the area of pneumonitis to be smaller and no evidence of an abscess could be seen He was by this time extremely well His temperature settled within two days of beginning the sulphapyridine and all physical signs disappeared At the beginning of treatment his blood sedimentation rate by Payne's method was 27 mm at the end of an hour, but had fallen to within normal limits (6 mm) before he was discharged The patient's condition continued to be satisfactory, and on Oct 21 a radiogram showed normal lung fields, with no evidence of abnormality at the right apex He was discharged twenty two days after admission apparently completely cured

This patient was a doctor, who reported sick as soon as he noticed that his sputum tasted foul He was admitted to hospital immediately, and thus attention was rapidly drawn to his small acute abscess in its unusual situation at the extreme apex of the right upper lobe The success of sulphapyridine is not therefore beyond dispute in this case, for it might be argued that small acute lung abscesses are not rare so much as unrecognised, and may heal spontaneously The fact remains, however, that after the course of treatment the abscess and surrounding area of inflammation disappeared entirely within thirteen days

My thanks are due to the officer commanding the military hospital for permission to publish this case

Medical Societies

ROYAL SOCIETY OF MEDICINE

At a meeting of the Section of Neurology on March 19, with Prof GEOFFREY JEFFERSON in the chair, a discussion on

Fat-embolism

was opened by Dr A H T ROBB-SMITH He described fat-embolism as a condition in which fat, circulating as globules in the blood-stream, occludes capillaries and creates multiple foci of anoxæmia After tracing briefly the history of its discovery and experimental production he showed, from figures in his own series of autopsies performed on accident cases, that the condition is far commoner in this country than has been generally recognised He attributed the lack of recognition to the less systematic pathological examination of such cases here than on the Continent and in America Fat-embolism is usually due to gross trauma, and, from his experience, Dr Robb-Smith regards it as playing a significant part in the fatal outcome in 25% of cases, though this assessment cannot be other than arbitrary The extent of the trauma is important and fat-embolism is most frequent in association with multiple fractures, especially those involving long bones But the condition may also be found in cases in which the skull alone has been fractured or even where no fracture has occurred Thus it may complicate severe burns, though it is then usually slight in amount, and it may follow manipulations or the therapeutic injection of oily solutions It is a frequent complication of poisoning by ammonia and other alkalis

Dr Robb-Smith went on to discuss the controversial subject of the source of the fatty material and the means whereby it enters the circulation He considers that the history in most cases favours a local rather than a hæmic origin of the emboli He then described the clinical picture of pulmonary fat-embolism In a classical example there is an early stage of shock which, having been dissipated by treatment, is followed after a variable latent period by dyspnœa, cyanosis and pains in the limbs with a sense of thoracic constriction These signs and symptoms are accompanied by a rise of pulse-rate, respiration-rate, and temperature, but no fall in blood pressure Examination of the chest reveals a few ra but no signs of consolidation and there may be a littl frothy sputum These are the signs of acute pulmona œdema and the patient may die in this anoxæmic pha from right-heart failure Usually, however, the se of the symptoms diminishes, the respiration-rate high and signs of pneumonia develop In this stage a true pneumonic consolidation may result from a secondary infection No diagnostic aids give an unequivocal answer in connexion with pulmonary fat-embolism The morbid anatomy is distinctive when once it has become familiar , a useful test is to take a thin shaving of the lung tissue, clear it for a few minutes in 2% potash solution and then examine it under the microscope, when th emboli can be clearly distinguished as refractile dr and cylinders Symptoms of systemic fat-embolism develop a few days after the accident , they are characterised by a delirium which is often violent, alt with stupor and merging into coma , hyperpyrexia is the rule and petechiæ may appear in the skin of the neck, chest and arms Lumbar puncture shows no constant changes, though fat has been described as a constituent of the fluid Examination of the optic fundi may reveal segmentation by fat of the columns of red cells in the vessels and associated hæmorrhages Fat may also be demonstrated in the urine

Outlining the treatment of fat-embolism in general, Dr Robb-Smith recommended, on prophylactic grounds, that the immobilisation of fractures should be as complete as possible and that a tourniquet should be applied during manipulation and released slowly afterwards The administration of oxygen during the stage of pulmonary œdema is helpful and the subcutaneous injection of adrenaline should be tried Intravenous therapy is inadvisable at this stage Sodium desoxycholate has been tried on one patient, but although the pulmonary symptoms improved cerebral fat-embolism and death followed later Animal experiments are in progress with this substance and so far it appears to be harmful Dr Robb-Smith emphasised the need for a wider recognition of the clinical manifestations of fat-embolism , further study may thus lead to more rational forms of therapy

Dr DOROTHY RUSSELL outlined the clinical and pathological features of two cases of cerebral fat-embolism In the second of these a severe head injury, which had received effective surgical treatment, was associated with trauma elsewhere The diagnosis of fat-embolism in such cases may be very difficult In addition to the numerous foci of necrosis and hæmorrhage in both cerebral cortex and white matter associated with capillary fat-embolism, which have been widely recognised as characteristic features, Dr Russell drew attention to the great concentration of emboli in the choroid plexuses These had led, in both cases, to widespread degeneration of the epithelium and she suggested that the cerebrospinal fluid should be examined more critically for what might prove to be diagnostic changes A similar change in the plexuses has been observed by Fazekas in experimental fat-embolism produced by ammonium and sodium hydroxide poisoning An unusual feature in one case was a large anæmic infarct in an occipital lobe due to thrombosis of an adjacent meningeal artery

Dr J G GREENFIELD described a case of cerebral fat embolism in which hæmorrhages were not conspicuous in the brain although emboli were abundant The subcortical white matter showed numerous sharply defined perivascular areas of demyelination In the cortex these were represented by areas of necrosis which, again, presented rather definite borders

Mr A H HUNT pleaded for the wider recognition of fat-embolism in differential diagnosis The multiplicity and changeability of the initial signs and symptoms are characteristic of the condition He has observed recovery from cerebral fat-embolism in a man of 29 who, at an early stage of his illness, developed right hemiplegia and became comatose Bilateral exploratory craniotomy was performed, and on the fifth day petechiæ appeared in the skin and fat in the urine From the seventh day he began to improve and became mentally normal within a month Since then he has retained good intelligence and memory but sleeps little and has developed headache on resting

In the discussion that followed Dr ROBB-SMITH said that the fat in fat-embolism is probably derived from the traumatised areas but it is possible that fat is freed, at an early stage in subjects suffering from trauma, through the action of a lipoproteinase No anæsthetic was given in most of the examples forming his series but there is experimental evidence that the administration of ether diminishes the number of emboli When the ether was dispersed, however, more emboli appeared than in controls, so that this form of treatment cannot be advised as a prophylactic measure —Dr ERIC GARDNER noted that fat-embolism appears more frequently in the young than in the old; Dr ROBB-SMITH agreed, but he had found that fatal injuries are in general more common in the early decades —Dr D DENNY-BROWN asked for information about the time required for the development of changes in the myelin in these cases Examples have been reported in the literature as " delayed concussion " which were almost certainly due to fat-embolism He noted that petechial hæmorrhages are a feature of both conditions

LIVERPOOL MEDICAL INSTITUTION

AT a meeting of this institution on March 6, with Prof O HERBERT WILLIAMS, the president, in the chair, a discussion on

War Neuroses

was opened by Dr WILLIAM JOHNSON He said that in anticipation of cases occurring amongst civilians as a result of air-raids an E M S centre was opened in Liverpool early in the war Instructions were circulated by the group officer to first-aid posts and receiving hospitals with suggestions for dealing with patients in order to limit the number admitted to the centre As it turned out there was a dearth of civilian cases and not a single one has been admitted to the centre This experience is very similar to that in other centres After the evacuation of Dunkirk a group of military patients was admitted comprising types the same as those admitted to a centre in France during the battle of Passchendaele The majority of cases admitted to the centre in the past eighteen months have been soldiers who have not served outside this country Some were army misfits, others needed grading into lower categories, and some after treatment were fit to return to their units With regard to the latter a follow-up system is being carried out Those whom it was found necessary to board out of the Army were chiefly among the misfits, and men who had suffered from neuroses in civil life In the centre the *hospital* atmosphere is as far as possible excluded Very few patients are kept in bed, and a routine programme is in operation which ensures that patients are occupied through the day Physical-training instructors, occupational therapists, and instructors from among N C O patients have been appointed Carpentry, basket-work, raffia work, weaving, squad drill, route marches, games and talks on military subjects are contained in the programme It is important that military discipline shall be maintained in the centre

Dr F HOPKINS referred to the controversy which was waged in the medical journals some months ago on the subject of treatment in neurosis centres, and said that the real issue now is *whether* patients should be treated from the viewpoint of one particular school of medical psychology—the psycho-analytic—or by more flexible and practical methods of applied psychology The choice and carrying out of psychological treatment is important, but it is but one of the functions of the psychiatrist, diagnosis, prognosis and disposal was equally important, for only a relatively small proportion of cases require or are able to benefit by anything other than the more superficial kinds of treatment In every case admitted an estimate should be made of the optimum result possible before treatment is embarked on One of the most difficult problems is the disposal of the man who, though his disability may be slight, is unlikely to be a satisfactory soldier on account of personality type and attitude to service, but who might be an adequate civilian worker

Dr S BARTON HALL considered it important to determine as early as possible a man's fundamental attitude towards military service, as distinct from that outwardly expressed, since thereby much unnecessary effort, waste of therapeutic skill, inefficient service, and friction in the military machine, not to speak of expenditure of public money, could be saved In 150 consecutive cases of neurosis investigated, few of which were acute, the attitude towards service was at the outset found to be unsatisfactory in 78 Of these, only 2 could be rehabilitated to a degree sufficient to enable them to return to their units On the other hand, of 24 patients whose attitude towards service was found to be satisfactory 21 returned to their units with in many cases excellent prospect of rendering further useful service Among those whose attitude to service was unsatisfactory, a relatively high proportion were men, often over the age of 40, who had previously served in the Army, and even been invalided out and pensioned from it during the war of 1914–18 Of 33 soldiers referred for psychiatric investigation as outpatients, 11 were found to be mentally defective, though previously unascertained, and in 2 others intellectual development was so retarded as to incapacitate them for military training or service in any grade The anomaly in the examination of recruits thus revealed is of grave concern for the Army, and it reveals a serious defect both in the application of provisions for ascertainment of mental defect in the Education and Mental Deficiency Acts and also in the system of medical education whereby a board of medical men can pass men so handicapped as suitable for military service

Dr N S ALCOCK said that the essential in running a war-neurosis centre is the combination of physical and mental management In the initial interview the attitude of the patient is determined First it is decided whether he should be allowed to mix with the other men in the centre, or whether, as in hysterical patients, symptoms must be removed before he can join in the activities of the centre Secondly, occupation is discussed—what the man can do to help in the occupational programme and what type of occupation will most benefit him Lastly, he is allocated to his medical officer In running the centre every endeavour is made to make it approximate as nearly as possible to life in the units The part played by the N C O patients in running the occupational programme should be emphasised both for their own treatment and readjustment and also to get nearer the army life Patients should not spend too long in other hospitals before coming to the centre, or their previous hospitalisation will form a serious handicap to their fitting in with the running of the centre Unless there is a fairly close approximation between life in the centre and in the Army the adaptation the men make may be of little help when they return to the Army

Surgical Problems of War Casualties

In opening a discussion on surgical problems, Prof T P MCMURRAY said that the outstanding feature of the surgery of the present war, as compared with the last, is the almost complete disappearance of the ward dressing trolley and the ward gas apparatus The appalling pain caused by the daily or twice daily dressings has gone, and in its place is the modern technique of excision and fixation Fixation is almost always by plaster-of-paris, though in wounds of the thigh in fat women complete fixation by this means is extremely difficult An addition to the technique is the use of sulphanilamide by packs or in powdered form, or by insufflation on the surface of the wound Although sulphanilamide has helped to prevent sepsis in some cases which have not come for operation for 4–8 hours after the infliction of the wound, nothing can replace perfect excision of the wound, which is the essential point in treatment *It is criminal* to suggest that excision can be done badly so long as sulphanilamide is used The main problems met with now are shock, for which treatment is almost *standardised*, sepsis, the prevention of which depends largely on *excision* of infected and dead tissues and wide opening up of tissues which have become infected, and fractures of the pelvis, which have been common owing to the falling in of bombed houses In many cases of fractured pelvis there is a rupture of the urethra, and it would be well if agreement could be come to on the ideal treatment for this complication Are patients with a ruptured urethra to be treated with a catheter in position, or by suprapubic cystotomy, and what are the advantages of each? Professor McMurray warned those who apply plaster-of-paris without much experience that though this is a safe method of treatment so long as it is applied smoothly and without pressure, yet if skin-tight plaster is used on a limb the patient should not be transferred from the hospital for at least 48 hours During that time any abnormal point of pressure can be diagnosed and the pressure relieved, but if the patient is allowed to go home or to another hospital soon after the application of the plaster tragedies may happen

The PRESIDENT said that in rupture of the urethra it is necessary to differentiate between the intrapelvic and extrapelvic varieties In the former the urine escapes into the pelvic cellular tissue behind the triangular ligament, in the latter the escape is into the tissue of the perinæum in front of the triangular ligament It is the intrapelvic variety that occurs usually in fractured pelvis To establish the diagnosis of such a rupture it will be necessary to pass a catheter This should be done extremely gently, for more likely than not the tip of the instrument will pass through the rupture into the pelvic cellular tissue and this will tend to spread infection Even if the catheter does pass beyond the rupture into the bladder drainage will be inadequate, urine can still pass along the outside of the catheter and further infect the peri-urethral tissue Immediate suprapubic cystotomy and suction drainage is the rational line of treatment to follow in these cases

Mr F RONALD EDWARDS said that plasma is still not always being used in sufficient quantities, and a very rapid increase in blood-volume is necessary in severe cases of shock This can only be obtained by forced plasma administration with multiple cannulæ Oxygen therapy by the B L B, mask in shock is sadly neglected and this may turn the scale in a desperate case Desoxycorticosterone should be given a fuller clinical trial in shock There seems to be difference of opinion as to how and when to give sulphonamides in war injuries Certain wounds cannot be satisfactorily excised without producing a deformity out of all proportion to the original injury Many wounds come into close relation with important vessels and nerves which cannot be excised and are still potentially infected The sulphonamides seem to exert a definite inhibitory effect on anaerobic infection, and for this reason should be inserted into the primarily excised wound With wounds which are already grossly infected local sulphonamide tends to be washed away by the discharge, and it is then better to administer the drugs by mouth or intramuscularly, so that they will reach the organisms deep in the wounded area via the blood-stream If possible, estimations of the concentration in the blood should be done, a level of 10–15 mg per 100 c cm being maintained The incidence of gas gangrene is low—0 5% in the Liverpool area, with a fatality of 40% Tetanus has not been seen In perforating abdominal wounds, patients with involvement of solid viscera only as a rule do well, but in those with perforation of the alimentary canal submitted to operation the fatality is over 90% These patients die from shock not peritoneal infection, and further work is needed on the action of sulphonamides in the peritoneal cavity to stay infection, so that shock may be more efficiently treated before these people are operated on

---

Reviews of Books

Practical Public Health Problems

By SIR WILLIAM SAVAGE, M D Lond, examiner in the Universities of London and Wales London J and A Churchill Pp 198 10s 6d

THIS practical guide to problems in general hygiene which confront every medical officer of health will be especially valuable to those recently appointed who find difficulty in practising in the field what they have learned in the books and the laboratory Sir William, from his great experience in the work of a medical officer, in research, and in the examination of candidates for diplomas, knows where failures in preventive medicine are likely to occur and in this book he tells us how to avoid them Especially good are the chapters on water, milk and investigations of food-poisoning outbreaks The book is concerned only with basic hygiene and makes no mention of school medicine, maternity and child welfare and other burdens which in recent times have been laid on the medical officer In the preface Sir William Savage calls himself "an old timer bred in the old tradition," but his book is completely up to date

Modern Medical Therapy in General Practice

Edited by DAVID PRESWICK BARR, M D, LL D, Busch professor of medicine, Washington University, physician in-chief, Barnes Hospital, St Louis London Baillière, Tindall and Cox Three vols Pp 3661 £9 12s 6d

TEXTBOOKS of therapeutics are apparently in the fashion This big one, which has 106 contributors, is designed for practitioners and covers "the non-surgical treatment of disease" The first volume deals with general therapy, including the use of drugs, vaccines, sera and physiotherapy, and ends with the treatment of deficiency diseases and diseases of metabolism and allergy The second volume opens with a section on infectious diseases and thereafter describes diseases of the different systems In any book of this wide scope and with so many contributors repetition is difficult to avoid, but here the editor has performed his task well Most of the sections are excellent and specialists as well as general practitioners will find the book a source of authoritative information The general index, an important part of a book of this kind, is comprehensive and occupies nearly 100 pages

A Short Practice of Surgery

(5th ed) By HAMILTON BAILEY, F R C S, and R J MCNEILL LOVE, M S, F R C S London H K Lewis Pp 1016 30s

THE additions and alterations to this work are mainly minor Many of the contributions to surgical knowledge within the last two years which are of established value have been included, chemotherapy being given, as it deserves, an important but not too prominent a place As in earlier editions more importance has been attached to pictorial than to verbal stimuli, and a large number of new illustrations have been added, though some have been retained which might well have been discarded The historical footnotes which first appeared in the last edition have been multiplied, flavouring pleasantly the routine of study The chapters on genito-urinary surgery remain very good indeed, and those on the abdomen, mouth, neck and breast are also well done Although other sections—notably those dealing with fractures and general surgical pathology—do not reach this level, the book as a whole will certainly maintain its popularity with undergraduates

Speech Training for the Deaf Child

By SYLVIA M MARTIN, associate of the British Society of Speech Therapists London George Allen and Unwin Pp 114 5s

IN war the physically disabled are apt to be neglected, but there is always someone who has their well-being in mind Miss Martin has written this book to guide intelligent parents in the speech-training of their deaf children It was needed in peace-time when deaf-mute clinics for preschool children were few and far between, still more is it needed now when social organisation is more difficult The book is presented in concise and clear form The general advice and particular instructions encourage the parent to proceed step by step to a final success Not only is speech aimed at but normal speech with pure vowel and consonant discrimination and normal inflection The gradation of exercises is admirably arranged for this purpose At the same time they are simple and with patience can easily be carried out The consultant, the general practitioner, and the speech therapist may justly recommend this book Its use will allay an attitude of hopelessness in the parent and prevent the wastage of the early years for training purposes

VITAMIN B$_6$ DEFICIENCIES

Some recent findings . . .

CLINICAL experience, following biological experiment, has shown the usefulness of aneurin (B$_1$) in many conditions now known to be signs of dietary deficiency. Increasing the regular daily intake of Vitamin B$_1$, by the use of Bemax, not only improves the general health but also prevents the recurrence of the deficiency symptoms

Considerably less is yet known about Vitamin B$_6$, but biological experiments with the pure vitamin have proved useful in various syndromes. Improvement has been recorded in certain cases of idiopathic epilepsy, in amyotrophic lateral sclerosis, and in hypertrophic muscular dystrophy. Decreased stiffness and rigidity have followed its use in non-postencephalitic parkinsonism

The particular deficiency symptoms which have responded to Vitamin B$_6$ administration are extreme nervousness, insomnia, irritability, cramping abdominal pain, muscular weakness and rigidity with difficulty in walking

Bemax is probably the richest of all dietary sources of Vitamin B$_6$ and its regular use should therefore be of real benefit to patients showing groups of the above symptoms and signs.

The Vitamin and Mineral Constituents of BEMAX

	Approx daily human requirement	*One ounce Bemax supplies*	
		weight	*% of daily requirement*
VITAMIN B$_1$ (aneurin)	mg 2.0 (666 i.u.)	mg 1.2 (400 i.u.)	60

LONDON: SATURDAY, MARCH 29, 1941

THE PREVENTION OF GAS GANGRENE

THE cause of gas gangrene is, as OGILVIE[1] has remarked, a particular opportunity rather than a particular organism. It requires first, an infected soil (the infecting anaerobes are often present on soiled clothing); secondly, a deep wound of muscle (rarely areolar tissue as in the retroperitoneum) usually caused by bomb or shell splinters; and thirdly a time interval of 12–24 hours between wounding and surgical treatment, although fulminating cases may develop within a few hours of injury. The first two requisites are generally accepted but it is not so widely recognised that time as a factor in establishing infection is probably more important in gas gangrene than in any other disease. The patient's life may depend on his being surgically attended within 12–24 hours of wounding. Wherever there has been delay in the treatment of war wounds gas gangrene has become a prevalent infection, an experience dearly won in the 1914–18 war. With air-raid casualties there should theoretically be little delay in treatment, but various circumstances may combine to interfere with adequate surgical attention within the safe period, and in fact clinical gas gangrene has been cropping up in a number of hospitals dealing with civilian casualties; rates of 0·5 and 2·7% have been quoted but the incidence depends a good deal on the nature and severity of the casualties. If it is granted that early surgical débridement, admittedly the best prophylactic if properly carried out, is not always possible, other available methods for the prevention of gas gangrene must be used. Because gas-forming anaerobes kill by the toxins they produce, gas-gangrene antitoxin might reasonably be considered the prophylactic of choice. Yet it has never become popular; indeed, in the early period of this war an official circular forbade its use prophylactically for air-raid casualties. Surgeons found they could dispense with it in civil practice, and TRUETA'S experience with air-raid casualties and other war wounds in the Spanish civil war—1 case of gas gangrene among over 1000 patients—strengthened opinion against its use. Some go further and say that as a prophylactic gas-gangrene antitoxin is ineffective, although it is difficult to find on what grounds this view is based. Only one large-scale experiment on the prophylactic use of *Cl. welchii* antitoxin has been recorded, and the findings were on the whole favourable. In France in 1918 alternate divisions were issued with either ordinary antitetanic serum or this with the addition of a low-titre *Cl. welchii* antitoxin, and one or the other was given as a prophylactic to all the wounded. The results were as shown in the following table:[2]

To quote ADRIAN STOKES: "The experiment demonstrates what would naturally be expected, that the number of cases occurring in the casualty clearing stations was not influenced and that the incidence at the base was probably diminished. The period between the administration of the prophylactic serum and the recording of the presence of gangrene at a casualty clearing station would often be a matter of only a few hours, and also those cases which had been lying out, or whose evacuation had been delayed owing to military conditions, and in whom the gangrenous process had probably begun at the time of the injection of the serum, are included in the C.C.S. records. On the other hand, the mortality in cases arising in base hospitals was reduced by about 50%. It must also be remembered that only one of the pathogenic organisms was prophylactically dealt with in this series." On the experimental side there is abundant evidence, supported anew by Dr. GORDON and Professor McLEOD in this issue, that antitoxin is effective when used prophylactically. If it is given some hours after infection the results are less uniform, being as a rule better in infections with *Cl. welchii* than with *Cl. septique*, which may be due to the fact that *Cl. welchii* is more toxigenic than invasive, whereas *Cl. septique* is both toxigenic and invasive and therefore less amenable to the action of an antitoxic serum. Infection with *Cl. œdematiens* (*novyi*), which is mostly toxigenic, should be readily prevented by the specific antitoxin.

—	No. of men	Cases of gangrene	Deaths	Morbidity per 1000	Fatality (%)

A.T.S.	23,792	92	21	3·86	22·62

* A.T.S. & W. = antitetanic serum plus antitoxin for *Cl. welchii*
† A.T.S. = ordinary antitetanic serum

The advent of this war gave a fresh impetus to research on the prevention and treatment of experimental gas gangrene with the sulphonamide drugs which had already worked miracles in other infections. Early investigations, though encouraging, were mostly carried out on animals infected intraperitoneally and thus did not closely resemble the natural infection. When injected intramuscularly, the gas-forming anaerobes produced infection which was unaffected by sulphanilamide and only partially prevented by sulphapyridine when these drugs were given by mouth, intramuscularly or intraperitoneally. They had no therapeutic value in established infections. Since then there have been two valuable additions to the armoury—sulphathiazole, and the local application of sulphonamides to the injured and infected muscle. In the test-tube sulphathiazole seems to be superior to the other sulphonamides in its action against gas-forming anaerobes, and it has the advantage over sulphapyridine of greater solubility, which allows a higher concentration in the wound-fluids when applied locally. Allowing for differences in technique—the methods used by McINTOSH and SELBIE[3] and by REED and ORR[4] closely resemble the natural infection—the evidence from recent investigations indicates that sulphathiazole is the most generally effective as a prophylactic, that local application gives better results than administration by any other route, that used locally sulphanilamide is better than sulphapyridine, and that in themselves these drugs have hardly any curative value, with the possible exception of locally applied sulphathiazole On the basis of these results, HAWKING[5] has recommended a mixture of sulphanilamide and sulphathiazole in the proportions of 2 to 1 for local application as soon as possible after wounding The amount of drug recommended for local use has usually been 5–15 g, but in view of the low blood-levels found clinically after such doses and the relatively big doses required to prevent experimental infection, larger amounts, say 20–30 g, could probably be safely applied, although too little is yet known about the effect of these drugs on the shocked patient

One difficulty with local chemoprophylaxis is that it is usually not attempted until the patient is being dealt with surgically, by which time gas gangrene may be in its incipient stage and beyond drug control The insufflation of a sulphonamide powder should be supervised by a surgeon and as a rule must be done under anæsthesia, in a shocked patient resuscitation must come first Gas-gangrene antitoxin, on the other hand, can readily be given intramuscularly along with tetanus antitoxin as soon as the patient is attended medically If this is done, as it should be whenever there is a deep injury of muscle, it may not always prevent local gangrenous infection, but at least the surgeon will be able later to do the toilet of the wound on a non-toxic patient In this war, as in the last, incipient gas gangrene has been misdiagnosed as persistent shock, and operation delayed till it was too late A point which GORDON and MCLEOD mention—and which was stressed in THE LANCET War Primer on Wound Infection (p 25)—is that much larger doses of antitoxin than are ordinarily prescribed will be needed to combat an infection already begun but not detected clinically A local barrage of antitoxin has been suggested when infection is present or suspected, but the intravenous route is likely to be most effective for antitoxin used therapeutically For the declared case, a combination of drug and serum[6] will be the most effective supplement to surgical treatment and may lead to more conservative surgery And, if the results of treatment are to be accurately assessed, every surgeon must learn to distinguish wounds infected with anaerobes from true gas gangrene,[7] in which there is an invasion of tissues not already damaged, with death and putrefaction of previously healthy tissue

PRESUMPTION OF DEATH

IN the Probate Court last week the President granted leave to swear the death of Mr Alphonse Abrahams, a diamond broker, as having occurred last September when he was in a shelter which was bombed Mr Abrahams, it was proved, had permission to shelter in the basement of a clinic adjoining his flat, he had undressed, put his belongings on a table and inflated a rubber mattress After the explosion (which seriously damaged the basement) his wallet and fragments of the mattress were found but there was no trace of Mr Abrahams Soon after the President's decision was reported a widow wrote a letter to a newspaper to complain that, her husband having volunteered for civil defence work as an A R P stretcher-bearer and his depot having been bombed last September, she had to wait three months for the certificate of presumption of death and was still waiting for her widow's pension His body had not been recovered Unhappily there will be many of these distressing cases, and, while the assistance authorities are known to be doing their best to relieve immediate needs, there is bound to be some delay Defence Regulation 30A, just published, will help A coroner will be able to hold a private inquiry, without a jury, where a body is believed to have been destroyed by enemy action He will issue a certificate to that effect, and the registrar will then issue his certificate in the usual way

Peace-time provisions for presuming death are naturally inadequate in present conditions Ordinarily in civil, as in criminal, proceedings there has been a cautionary rule that it is unsafe to accept the fact of death without the finding and identification of the dead body There was in England no common-law or statutory limit to the presumption of the continuance of life, but the analogy of the criminal law of bigamy introduced a presumption of death after a period of seven years' absence After the seven-year period the courts could look back in order to see whether death could reasonably be presumed to have occurred earlier, there was no presumption that death occurred on the last day of the period For the purpose of granting probate the court has never insisted on waiting seven years if the missing person disappeared in circumstances which raised a strong possibility of death—for instance, if a ship had gone to sea and never reached port In recent years there has been a greater readiness to deal with presumption of death by statute In 1925 it was enacted that henceforth, where two persons died in circumstances which made it uncertain which of them survived the other, the younger would be deemed to have outlived the older Under the Herbert Act in 1937 it became possible for a married person, alleging the existence of reasonable grounds for supposing the death of the other party to the marriage, to petition the court for a decree of presumption of death and dissolution of the marriage In this connexion seven years' absence is prima-facie evidence of death if the petitioner has no reason to believe that the other party has been living within that time

The tragedies of the war have created fresh problems, and there must be legal safeguards still where rights and property are affected Trustees, for instance, cannot be expected to act upon statements which may turn out to be unfounded Soon after war began, Parliament passed the Execution of Trusts (Emergency Provisions) Act Nobody is to be deemed (for the purpose of that act) to have actual notice of any other person's death by reason only of a report that the other person is missing, or "missing, believed killed," unless the death has been presumed by order of a competent court and the person in question has notice of the order The new defence regulation seems to allow coroners to usurp the functions of the High Court

HALLUCINATIONS

LITERARY descriptions of hallucinations are plentiful not only in the archives of mental hospitals but also in accounts of religious or "psychic" experiences and in the autobiographies of poets and scientists Many writers on this subject—which lends itself readily to philosophical treatment—have found confirmation of their special theories among the abundant material Others, distrusting all observations but their own, have tried to gain information at the source by questioning and examining hallucinated patients But the reports of such patients are not often satisfactory, judgment and memory seem to be impaired during the hallucinatory phase as they are in the normal dreaming sleeper, and descriptive ability is rarely adequate Owing to the vagueness and indifference of verbal descriptions, one school has concluded that hallucinations are not in any way specific that they are merely vivid images identical with the mental mages of any normal person, important and significant to the patient only because of his disturbed mental condition This school puts emphasis on the psychological background rather neglecting the sensory element in the hallucination Others suspect that unsatisfactory descriptions may be a natural outcome of the strange appearance presented by many hallucinations which—according to this theory—differ so much from the real world to which our language is adapted that words prove inadequate to describe them, and patients, even after recovering their critical faculties, form new words or use comparisons which are difficult to understand

The strangeness of hallucinations, and the unreliability of polished literary witnesses, have been largely confirmed since the discovery of mescaline, the active principle of a plant used by Mexican Indians for many centuries in their religious ceremonials By injecting mescaline it is possible to change a person, for a few hours, into a hallucinated psychotic There is no danger of addiction, as with opium or hashish, and the few after-effects of the experiments are slight The application of these artificial psychoses to the study of psychological medicine is far from being exhausted Mescaline hallucinations are predominantly, but not exclusively, visual, consciousness remains relatively clear throughout a great part of the intoxication Nevertheless, even trained observers find difficulty in giving a description of what they have experienced, and complain of lack of suitable expressions MACLAY and GUTTMANN[1] gave the drug to artists and asked them to sketch what they saw and to make other drawings in retrospect It is striking that many of the peculiarities of the drawings thus obtained can be explained in terms of sensory physiology Fretwork patterns resembling the choroid capillaries, tapestry picturing the retinal artery and its branches, patterns similar to coloured scotomas or the fortification patterns seen by patients with migraine—these seem to point to a peripheral origin of mescaline hallucinations Other pictures illustrate the development of hallucinations with definite shape and content out of repetitive photomas or vivid after-images, a symptom also experienced by patients suffering from lesions of the occipital cortex The useful sensory deception that things around us are still and constant in shape can break down under mescaline, nothing stands still, everything fluctuates in some phases of the intoxication and in others the faculty to see actual movement is suspended Visual perceptions as well as hallucinations seem to change their shape incessantly for instance, when attention is directed on a special point the hallucinated figure seems to elongate itself in that direction

Mescaline intoxication thus supports the school which lays emphasis on the sensory peculiarities of hallucinations On some people it makes a deep and lasting impression, especially on artistic subjects who speak of the experience as opening up new access to the visible world This is of interest to those who like to speculate about primitive powers of sensory perceptions which may have been sacrificed to abstract thinking during human evolution Hallucinations of poets philosophers and religious ecstatics are, according to this view, produced by regression to a more primitive, but not necessarily less efficient, mode of experiencing[2] However that may be, the vividness of the experience explains the original use of the drug for religious purposes and throws light on the attitude of many psychiatric patients towards their hallucinations

HALLUCINATIONS

LITERARY descriptions of hallucinations are plentiful not only in the archives of mental hospitals but also in accounts of religious or "psychic" experiences and in the autobiographies of poets and scientists. Many writers on this subject—which lends itself readily to philosophical treatment—have found confirmation of their special theories among the abundant material. Others, distrusting all observations but their own, have tried to gain information at the source by questioning and examining hallucinated patients. But the reports of such patients are not often satisfactory; judgment and memory seem to be impaired during the hallucinatory phase as they are in the normal dreaming sleeper, and descriptive ability is rarely adequate. Owing to the vagueness and indifference of verbal descriptions, one school has concluded that hallucinations are not in any way specific: that they are merely vivid images identical with the mental images of any normal person, important and significant to the patient only because of his disturbed mental condition. This school puts emphasis on the psychological background, rather neglecting the sensory element in the hallucination. Others suspect that unsatisfactory descriptions may be a natural outcome of the strange appearance presented by many hallucinations which—according to this theory—differ so much from the real world to which our language is adapted that words prove inadequate to describe them, and patients, even after recovering their critical faculties, form new words or use comparisons which are difficult to understand.

The strangeness of hallucinations, and the unreliability of polished literary witnesses, have been largely confirmed since the discovery of mescaline, the active principle of a plant used by Mexican Indians for many centuries in their religious ceremonials. By injecting mescaline it is possible to change a person, for a few hours, into a hallucinated psychotic. There is no danger of addiction, as with opium or hashish, and the few after-effects of the experiments are slight. The application of these artificial psychoses to the study of psychological medicine is far from being exhausted. Mescaline hallucinations are predominantly, but not exclusively, visual; consciousness remains relatively clear throughout a great part of the intoxication. Nevertheless, even trained observers find difficulty in giving a description of what they have experienced, and complain of lack of suitable expressions. MACLAY and GUTTMANN[1] gave the drug to artists and asked them to sketch what they saw and to make other drawings in retrospect. It is striking that many of the peculiarities of the drawings thus obtained can be explained in terms of sensory physiology. Fretwork patterns resembling the choroid capillaries, tapestry picturing the retinal artery and its branches, patterns similar to coloured scotomas or the fortification patterns seen by patients with migraine—these seem to point to a peripheral origin of mescaline hallucinations. Other pictures illustrate the development of hallucinations with definite shape and content out of repetitive photomas or vivid after-images, a symptom also experienced by patients suffering from lesions of the occipital cortex. The useful sensory deception that things around us are still and constant in shape can break down under mescaline; nothing stands still, everything fluctuates in some phases of the intoxication and in others the faculty to see actual movement is suspended. Visual perceptions as well as hallucinations seem to change their shape incessantly: for instance, when attention is directed on a special point the hallucinated figure seems to elongate itself in that direction.

Mescaline intoxication thus supports the school which lays emphasis on the sensory peculiarities of hallucinations. On some people it makes a deep and lasting impression, especially on artistic subjects who speak of the experience as opening up new access to the visible world. This is of interest to those who like to speculate about primitive powers of sensory perceptions which may have been sacrificed to abstract thinking during human evolution. Hallucinations of poets, philosophers and religious ecstatics are, according to this view, produced by regression to a more primitive, but not necessarily less efficient, mode of experiencing.[2] However that may be, the vividness of the experience explains the original use of the drug for religious purposes and throws light on the attitude of many psychiatric patients towards their hallucinations.

MEDICAL CARE OF WOMEN IN THE FORCES

APART from a transient increase during the early months, the expected rise in venereal infections since the beginning of the war has not occurred. The recruitment of large numbers of women and young girls to the Forces was not at first accompanied by the enrolment of an appropriate number of women medical officers. This was a cause of anxiety to many people. There was good evidence that most women hesitated to report suspected venereal infection to men medical officers, and delay in treatment from this cause seemed likely to provoke spread of infection without adequate control. The Medical Women's Federation felt strongly that women who were serving should be receiving suitable sex teaching from qualified welfare officers and from medical women who had special experience in social hygiene; above all that they should on request have access to a woman medical officer. The need was definite and quickly recognised and the Services began to appoint medical women, who are now sufficiently numerous to put the federation's aim within reach. It seems, however, that the women serving and the medical men who still have charge of their health in some units are not all fully aware of the opportunity open to them. Women medical officers are fairly evenly distributed over the country, and it should now be merely a question of planning to arrange interviews for those women who wish to be examined by a woman. This does not mean that the medical women appointed are as numerous as they might be with advantage. There are still vacancies unfilled and the list of volunteers submitted by the Central Medical War Committee to the federation for a final opinion is now exhausted. Medical women with appropriate experience may feel the time is ripe to offer it. Some who put their names down earlier were not considered because the work on which they were engaged seemed at the time to deserve precedence, but it may well be that as a result of population shifts some now find themselves released, and will care to send their names in again to the secretary of the federation. The amount of venereal disease among women in the Forces has so far been small and treatment is rapid and successful In the early months of the war women were occasionally dismissed on acquiring infection, a dangerous and scarcely defensible practice , but this is no longer so, unless there are other and more serious grounds for dismissal To provide adequate and sympathetic treatment is, of course, an important item in preventing the spread of venereal infections, but education which helps to develop social conscience and to promote social hygiene is equally essential The greatest safeguard may well have been provided by the arduous character of the training, which has left little time or zest for philandering

SKIN LINES AND HAIR TRENDS

THE lines of the skin were studied in considerable detail in the middle of last century by Simon[1] and Langer,[2] and were beautifully and fully described by Erasmus Wilson in his "Diseases of the Skin" They are usually known as Langer's lines The deep lines or creases are found over joints and other parts which move, and mark the more fixed points They are produced by bands of fibrous tissue running from the skin to the deeper structures and prevent the skin from slipping about like a loose glove J Grayson[3] has recently studied these cutaneous ligaments on the lateral aspects of the human (and animal) digits He finds that in addition to the bands of fibrous tissue dorsal to the vessels, running from the phalanges to the skin opposite the interphalangeal joints, as described by Cleland as long ago as 1867, other retinacula can be dissected volar to the vessels, running from the flexor sheaths to the skin These particular retinacula do not produce skin creases because in this particular situation the skin does not become folded upon itself in flexion and yet does not move in relation to the deeper structures Finer lines can be seen with the naked eye running in some instances transversely, in some longitudinally These are due to the peculiar disposition of the fibrous and elastic tissue in the corium The finest lines can be seen with a hand lens, and divide the skin into a series of tiny triangles, fitting together like a beautiful mosaic They are well seen on the back of the hands and webs, and are produced by the finer movements of the skin The skin lines are remarkably constant from individual to individual, though their minor variations produce the cult of palmistry and the science of fingerprint detection Wood Jones[4] calls them tension lines, a good term which indicates their importance to the surgeon An incision along these lines will heal with the minimum of scarring, whereas one made across them will not only gape when made but produce a wide scar when healed Oblique incisions illustrate the effect of elastic pull, by the tendency of one side of the wound to slide relative to the other, a point that has to be noted in suturing The result of ignoring the skin lines can easily be studied on the abdomen, where incisions are made at all angles, *more in relation to the direction of the muscle-fibres* underneath

The distribution of the human hair and its direction has also been studied by Erasmus Wilson and many others since The main arrangement of the hair on the trunk is based on a whorl in each axilla, from which the hair streams up towards the head and neck, down the arm, down across the chest and abdomen, and down the legs In the midline of the body (front and back) lines of convergence are thus produced, and in other situations lines of divergence Wood Jones has drawn a chart of hair distribution which differs in some respects from Erasmus Wilson's description The hair on the head is based on a whorl in the occipital region (sometimes double) and a whorl at the medial end of each eyebrow Bolk[5] has studied the distribution of the hair on t forehead and head of the human fœtus and finds that t hair patterns are innumerable, a fact which can readil be checked by observing differences in individuals as see them From these observations it is probable despite a general conformity to plan the hair streams the human body show much greater individual v than the skin lines, and Wood Jones makes it clear th there is no relation between them Various th have been propounded to explain the distribution of human hair, but none has met with general accep Direction is given to the hair by the obliquity with whi the hair follicle is set in the skin This may be thoug to be of little moment to the surgeon, but is of importance when whole thickness skin is to transplanted from one part of the body to the othe particularly on the face in the region of the eyebrow and eyelashes

RAPIDLY DEVELOPING SILICOSIS

IN most industries where silicosis is encountered, characteristic feature of the disease is the slowness w which it develops It is "insidious in onset, of g chronicity, occurring amongst workers who are e for years to the inhalation of siliceous dust"[6] contrast with this well-known picture is the silicosis abrasive soap workers, and certain men engaged in crushing of quartz and sand-blasting Where the centration of fine dust in the air is very high, and the inhaled particles are almost pure silica, a fibrosis may develop rapidly and even be fatal in short a period as a few months This form of the dis has been referred to as "acute silicosis," but it *a little inappropriate to describe as acute a cond* which takes at least several months to develop more accurate though perhaps cumbersome t "rapidly developing silicosis" was adopted by 1938 Silicosis Conference of the International Lab Office The total number of cases recorded is large , Ritterhoff[7] has lately reviewed them and adde two new ones, both from the abrasive soap industry Macdonald and others[8] reported the first two in this country in 1930 , Middleton[9] described 14 i 1936 These all occurred among young girls empl in a soap factory in Wales Pulmonary tuber appeared to be a complicating factor in 12 (proven in of them In the United States Chapman[10] des 3 and Kilgore[11] 6 cases, most of them fatal In abrasive soap industry finely ground silica is mixed powdered soap and alkali, and the view has repeat been advanced that the presence of the alkali h the toxic effect of the silica by increasing its solubility This view seems unnecessary, if not unlikely, because the occurrence of rapidly developing silicosis w there is no admixture of alkali with the dust Sand blasters working in poorly ventilated places—e g , th recently described case of McNally,[12] tunnel workers s as those in the Johannesburg sewers and at Gau Bridge in America[13]—may contract silicosis with all th classical features of the disease becoming apparent in very few years or even months Gardner believes that the "acuteness of the reaction is logically explained on high concentrations of fine free silica"

The lungs of workers dying from rapidly developing silicosis, or from some intervening infection, often show no gross appearance suggestive of silicosis , nodules are not seen on the pleural surface or on the cut surface, t microscopic examination reveals numerous minute icotic nodules The smallness of these nodules obably explains the fact that X-ray plates of the chests these workers may fail to reveal the typical shadows silicosis A not infrequent finding is the interesting metastatic silicotic nodules" of the spleen These e held by Ritterhoff to be foci of macrophages and ot typical nodules, but Belt[14] finds that they are histogically characteristic of silicosis They are small, ear and discrete, admirably suited to minute analysis, hereas lung lesions may be coarse and conglomerate hey show clearly, in fact, all the characteristic features the highly distinctive lesion of silicosis The cure for pidly developing silicosis is in the hands of the engineer dequate measures for the suppression of dust should, nd indeed have in many instances, brought the condition nder control Whereas it is difficult to bring the dust oncentrations in mines down to a non-dangerous level, is comparatively easy to suck away the dust rising om a process over which a man works in a stationary osition or to encase a man in a positive-pressure mask o that he breathes only air which is supplied from utside his dusty environment The admirable measures nstituted by the Factory Department of the Home Office ave done much in this country to make "acute ilicosis" a distressing medical memory of the past

MALARIA IN THE ARMY IN INDIA

As a cause of illness in the Army in India in 1939 nalaria has not only maintained the first place but has omewhat increased its incidence over that of a year earlier[15] For this increase the war was at least in part responsible by necessitating movements of troops, their early return from the hills and their distribution, outside established cantonments, in security posts, indeed that last factor in some instances gave 100% incidence in the autumn In cantonments antimalarial measures have been carried on with skill, enthusiasm and success, but on the other side of cantonment boundaries the story is different Within cantonments the "dry day," on which possible mosquito breeding places are emptied, is now accepted Men do not grumble at the trouble but at the wind which may carry-in mosquitoes from outside This emptying excludes water stocked with gambusia—local fish which, by feeding on mosquito larvæ, effect the same object well and with less trouble Sprays made from pyrethrum flowers imported from Kenya have proved valuable for attack on the adult insect, and the plants are now being grown in Cashmere and in India itself Although malaria is still the greatest cause of illness in the Army in India, in the last 15 years its incidence among British troops has fallen in Rawalpindi from 473 to 41 and in Lahore from 2245 to 392—9 out of 10 infections avoided

THE FOCAL ORIGIN OF MAMMARY CANCER

EXPERIMENTAL research into the nature and causes of cancer is making such rapid progress that current medical teaching on this subject perpetually needs review In the medical schools it is still commonly taught that cancer of the breast arises in a single focus, and surgeons base their treatment on this assumption The correctness of this practice cannot be doubted, but the assumption on which it is founded lies open to question on academic grounds Experiments have shown that œstrogens play a leading part in the causation of mammary cancer, and that in a susceptible animal a single cancer may develop although the agent has been carried to all parts of the breasts in the blood-stream The normal as well as the pathological reactions to an œstrogen often vary in degree in different parts of a single mamma—for example, if a mouse has been subjected to a continued excess of œstrogen, the various successive changes culminating in cancer may all be present simultaneously in different parts of the same breast Such local inequalities of response are seen in other organs which react to œstrogen The appearance of mammary cancer at a single point, therefore, cannot be used to disprove its dependence on such a generally distributed agent as an ovarian hormone circulating in the blood On the other hand, if this ætiology is accepted, we might expect the occasional occurrence of mammary cancer in more than one focus at the same time In mice, cancer of the breast, whether spontaneous or artificially induced by œstrogen, is often of multifocal origin, and more than one mamma may be the seat of a primary tumour In considering this fact one has to remember that the mammary system is much more extensive, relatively to the rest of the body, in the mouse than in woman In women separate and grossly distinct primary cancers growing simultaneously in both breasts or in different parts of the same breast are rare, though not unknown Another form of multifocal mammary cancer seems to be more frequent in women, that in which separate ducts or acini, within the same region of a mamma diffusely affected with precancerous changes, become the sites of malignant growth In this sense the occasional multicentric origin of cancer in women seems established Such an observation is not new, but fresh attention is drawn to the subject in a paper by Sir Robert Muir[1] on the evolution of mammary cancer, in which the occurrence of multifocal cancer is lucidly described and exemplified He also points out that a malignant change may affect diffusely the cells of one region of the mamma, in such a case the cancer may be described as regional rather than focal The implications of his remarks will doubtless have an influence on medical teaching, so that the student will be taught to regard the focal origin of mammary cancer not as a scientific fact but merely as an approximation to reality and as a gross but serviceable guide to the operator.

IS POLIOMYELITIS WATER-BORNE?

KNOWLEDGE of the epidemiology of poliomyelitis has advanced a long way from the time when the disease was regarded as a spontaneous atrophy of the anterior horn cells of the spinal cord But even after the infectious nature of the disease was proved, inquiry about the mode of spread was greatly restricted because the monkey was the only animal found susceptible to experimental infection, and case-to case spread was extremely rare However, with the help of the neutralisation test which demonstrated antibodies in a high proportion of urban communities, it became obvious that latent infection must be very common and that spread was presumably taking place by means of healthy carriers or abortive cases Indeed, accumulated data showed many similarities between poliomyelitis and diseases spread by direct contact or droplet infection but with this contrast, that whereas, in measles for example, 99% are clinically and 1% latently infected, the ratios are reversed in poliomyelitis But it is not all plain sailing Outbreaks occur which are strictly localised to one district and do not follow lines of human traffic, cases crop up simultaneously in a district without any apparent opportunity for spread by a human carrier and, most puzzling of all, whether it breaks out in England, America, Scandinavia or the Antipodes, poliomyelitis always shows a late summer or autumnal epidemic wave Add to that the gastro-intestinal upset which often ushers in the clinical disease, and the evidence of systemic infection with involvement of mesenteric glands, and it becomes difficult to say whether poliomyelitis should be grouped with the respiratory or the intestinal infections

[15] Annual Report on the Health of the Army in India for the Year 1939 New Delhi

[1] *J Path Bact* 1941, 52, 155

It has been known for some years that the virus of the disease could be recovered from the fæces of clinical case and healthy carrier, and that it may persist in the intestine for weeks or months after an acute infection The virus has also been recovered from sewage and in one unconfirmed instance by Kling from drinking-water[1] Following up their earlier work and using the technique they devised—intraperitoneal injection into monkeys of the etherised supernatant layer—Paul and Trask[2] have shown that the virus can be recovered from the stools not only of clinical cases but from patients with mild infections which could not otherwise be confirmed as poliomyelitis Furthermore, from a study of an outbreak in rural Connecticut, they concluded that the spread was connected with a particular river, and river epidemics in Sweden and Germany have been described by Kling Paul and Trask, therefore, carried out extensive tests for the virus in sewage From 66 samples, of which 13 gave unsatisfactory results, they isolated the virus at least 6 times, representing four samples of sewage from two different sites, one of which was the sewer pipe of an isolation hospital where cases of the disease were being nursed Two other points were established (1) that the total content of the virus in sewage may be large, and in this connexion they record in a footnote that monkeys can be infected by nasal instillation of unetherised fæces , and (2) that the virus is stable enough to be carried in sewage for at least an eighth of a mile From these findings Paul and Trask are cautious in drawing any conclusions They agree that there seems good evidence for the spread of poliomyelitis by direct contact, but they think there may be other channels including contaminated food, milk and water, and they direct attention particularly to the part which polluted watercourses may play in spreading the infection The epidemiological puzzle of poliomyelitis is still far from being solved, but perhaps we are beginning to find an explanation for its unusual seasonal distribution

MORE FAMILY BUDGETS

CONTINUING its analysis of the weekly budgets collected in 1937–38 the Ministry of Labour now gives a picture of the expenditure of the average agricultural worker, dietary studies of whom have been far less frequent than of his urban counterpart[3] The average size of the 1491 families contributing to the study is, rather unexpectedly, virtually the same as in the industrial households previously reported[4]—namely, 3 79 against 3 77 Their mean weekly expenditure is, however, substantially less, 57*s* 4*d* as compared with 85*s* The cost of housing in rural districts (rent, rates, water charges, &c) is naturally lower, 4*s* 9*d* per week against 10*s* 10*d* , though whether effectively less in relation to the amenities the family obtains for it is another matter —for instance, the urban household spends 2*s* 5½*d* a week on gas and electricity and the rural only 7½*d* , for they cannot spend on what is not there On clothing and footwear the average rural expenditure is 5*s* 3*d* a week, the urban 8*s* 1*d* , the former has the obvious advantage of a smaller expenditure on travelling and, as the returns show, the more doubtful advantages of a lower outlay on tobacco, newspapers, entertainments and doctors A greater proportion of the income has, of course, to go to food on which the average rural family spends 27*s* 9*d* , or 48% of the total, against the urban family's 34*s* 1*d* , or 40% The comparison, however, excludes allowances of food from employers or grown by the household, and this clearly much reduces the value of the comparisons one would like to make between urb and rural diets For example, from an early study the diets of rural workers in Essex,[5] Bradford Hill c cluded that at that date (1923) the rural diet was sufficient, though it compared favourably in respects with urban diets of families with larger incom owing to the home produce It was, however, varied, with a substantially smaller amount of meat considerably more bread and flour The Ministry Labour's budgets show the same tendency, but differences are narrow For instance, the av agricultural household spent 4*s* 2*d* weekly on bread ar flour and the industrial household 3*s* 6¼*d* , on me (including poultry, rabbits, bacon, ham, &c) the spent 7*s* 2*d* and the latter 8*s* 1¼*d* , while the figures sugar are 1*s* 3½*d* rural and 1*s* 0½*d* urban The items of food provided by employers are milk, and (in Scotland) oatmeal, while home produce mainly in potatoes, cabbages, and eggs, all impor items in a good diet From the figures available should be possible to build up a broad between the diets of the urban and rural groups, even though it be not complete it would be of interest

TERMINOLOGICAL EXACTITUDE

SPEECH, that late acquirement of the tool animal, has little precision as yet Even our most statements convey but a rough meaning, and scien terms—especially psychological terms—have often many interpretations as interpreters Some day speech may become as exact as mathematics , and in attempt, perhaps, to hasten that good time the injuries committee of the Medical Research Council hav published a glossary of psychological terms common used in head injury Their aim has been to greater uniformity in case notes and the definitions out are already in use at the special centres for the tre ment of head-injuries , if they were generally adopted the medical services the clinician attending a tran patient would derive an accurate idea of his state his notes Only sixteen terms are defined semicoma, confusion and delirium , traumatic and automatism , concussion , traumatic demen intellectual impairment and personality disorder malingering and hysteria , insight, judgment and co prehension , and amnesia The committee point that the definitions are arbitrary and may not universally acceptable, but rightly insist that to avo further ambiguity they should be accepted and After all, it matters little what a word means provided all agree on its meaning If we need new terms we always invent them neologisms are not the prero of the insane The other M R C committees might follow suit by defining their own terms, and in the we may get what we badly need—a good English glossa of scientific terms There are some excellent Am dictionaries, but they show troublesome divergences spelling and sense from accepted standards over h There would be an all-round gain if English scientific people could speak and write the same languag and a joint Anglo American committee on terminol is needed to bridge the gaps

MEDICINE AND THE LAW

Judicial Views of Medical Evidence

WHO shall decide asks Pope in an often-quoted line when doctors disagree? The disagreement of medical experts in the witness-box is often matter for judicial comment. But judges also disagree. In particular it seems, they differ about the value of the personal evidence of doctors. If Mr Justice Macnaughten be correctly reported, he declared last week that he had never yet come across an accident case where the evidence of a doctor in person was of any assistance at all though doctors' reports were generally most helpful. He was being asked to fix a day for a trial in which there would be a great deal of medical evidence. He refused to do so and he warned counsel that if it were found that the doctors' evidence could have been put in the form of reports costs might not be awarded even to a successful litigant. "It is a sheer waste of money and valuable time" he said "to bring doctors to court."

Against what is possibly an over-simplification of judicial experience, let us put the dicta of the Court of Appeal, delivered a few days earlier in the case of Proctor v. Peebles (Papermakers) Ltd. A young man had his hand crushed in the rollers of a machine. When sued for damages, the employers did not dispute their liability but they challenged the plaintiff's estimate of his injury. There had been the usual preliminary skirmishing before the case came on at the Lancaster assizes on a summons for directions to decide the lines on which the trial should proceed it had been ordered that the parties should agree the medical reports. At the trial Mr Justice Croom-Johnson commented unfavourably on the calling of a medical witness on behalf of the plaintiff in view of the projected arrangement that the medical evidence should be agreed. The Court of Appeal while somewhat vaguely anxious not to discourage preliminary agreement upon medical questions, announced that directions for agreed medical evidence should not be ordered as a matter of form. In Proctor's case said Lord Justice du Parcq, where prognosis was important the production of merely paper evidence was inappropriate. "It was most desirable that a doctor should be present in court to answer the questions which a judge might wish to ask, if for no other reason." It was very unfortunate added Lord Justice MacKinnon that a judge should deprecate the calling of a doctor in such a case, as it was often of the greatest advantage that the doctor should be present in order to explain what he had reported and to undergo cross-examination. In Proctor's case the doctor who was called on behalf of the plaintiff had stated his opinion that the injury to the young man's hand was permanent and without remedy. In the view of the Court of Appeal the trial judge ignored this uncontroverted evidence and substituted some opinion of his own. The plaintiff appealed on the ground of the inadequacy of the damages awarded to him. His appeal succeeded. Mr Justice Croom-Johnson had given him £550, the Court of Appeal increased this sum to over £1200.

It is not for doctors to decide when judges disagree. The medical witness will doubtless be grateful for any reform which saves him from wasting valuable time in the precincts of a court. Probably, too, he is conscious that the system which brings medical experts before a judge as members of opposing teams sometimes produces an unedifying spectacle. If he belongs to the plaintiff's side, he has come there to give evidence for the plaintiff, his sympathies have been enlisted by that side from the beginning; he has his reasons for his views; he wants to see those views upheld. If he is on the defendant's side, and especially if he be in the habit of giving evidence for defendants, sentiment will be out of place and scepticism in the matter of subjective symptoms will be inevitable and appropriate. Sometimes it is true the experts on both sides may meet in conference beforehand. But the reasoned convictions which they have come to court to support are not to be lightly abandoned after a few minutes' conversation. Nobody suggests that the medical witnesses are acting in bad faith, but they are identified with the side which invites their aid. We must expect the plaintiff's witness to assert that the injury is due to the accident and that the sequelæ are serious and permanent. We must expect the defendant's witness to maintain that the injury, if any, is unrelated to the accident, that it is greatly exaggerated and that anyhow, it will soon get right of itself. The authority of the law may direct the opposing teams to meet in consultation but it can no more procure agreement between witnesses than between the parties themselves. For years reformers have been advocating a greater use of medical assessors to relieve judges of the troublesome business of deciding medical issues. But the law is reluctant to surrender its jurisdiction. It is also, as so often appears in criminal trials where the irresponsibility of the insane is in dispute extremely suspicious of the intrusion of medical upon legal standards. The ideal tribunal perhaps would be the judge who is fully trained both in law and in medicine; but a strong legal element in the body which made recommendations a few years ago about the coroner's office deprecated any dual qualification and seemed to consider that only the barrister or solicitor untainted by any medical training could be trusted to hold an inquest. The law is for the lawyers unless perhaps the litigant is entitled to express his view. Courts after all, exist in order that plaintiffs may bring claims. Will the plaintiff still have perfect confidence in the course of justice if he is told that his medical witnesses must behind his back cobble up some compromise with the defendant's witnesses upon the matters of fact and opinion on which his case is founded?

TREATMENT OF BURNS

NOTES on the local treatment of burns, based on recommendations of the coördinating team on burns appointed by the war wounds committee of the Medical Research Council have been distributed by the Ministry of Health for the guidance of medical officers in E.M.S. hospitals and first-aid posts. The recommendations are as follows.

AT FIRST-AID POSTS

Minor burns which do not require admission to hospital should, after cleansing the surface with plenty of soap and water be dressed in the following way.

In the case of the face or hands, with gauze or lint impregnated with sterilised Vaseline.

To prepare sterilised vaseline dressings, half fill a biscuit tin with vaseline, stand the tin in a deep dish of water which is brought to boiling-point on a stove or fire. When the vaseline is melted, drop into it pieces of gauze or lint about 6 in. square, folded into two, until the tin is full. Add more vaseline if necessary to cover the dressings. Leave the tin in the boiling water for half an hour. Then remove, put on the lid and seal with a strip of strapping.

In other parts of the body, with tannic-acid jelly or gentian violet jelly, 1%. If jellies are used no dressing should be applied over the burnt area and clothing must not be allowed to come into contact with the burn area until the coagulum has formed and is dry. The application of tannic-acid or other coagulant jelly to the surface of a burn which has not been adequately cleansed is inadvisable.

Serious burns requiring admission to hospital should be treated by the application of sterile vaseline on gauze or lint to cover the exposed portions of the burn. It is hoped that in the near future a non-greasy substitute will be available for use instead of vaseline. Provided the patient is shortly to be transferred to a nearby hospital, no attempt should be made to remove clothing in order to expose the entire burn area. Serious burns always require injections of morphine for pain, in full doses (gr ⅓–½ for adults).

AT HOSPITAL

At the first hospital where the case can be fully treated the following lines of local treatment are advised for extensive burns of whatever degree.

Under gas and oxygen or Pentothal anæsthesia, the burn areas should be thoroughly cleansed by the gentle but liberal use of soap and water, followed by saline and by the removal of debris under strict aseptic precautions (soft soap should

It has been known for some years that the virus of the disease could be recovered from the fæces of clinical case and healthy carrier, and that it may persist in the intestine for weeks or months after an acute infection The virus has also been recovered from sewage and in one unconfirmed instance by Kling from drinking water[1] Following up their earlier work and using the technique they devised—intraperitoneal injection into monkeys of the etherised supernatant layer—Paul and Trask[2] have shown that the virus can be recovered from the stools not only of clinical cases but from patients with mild infections which could not otherwise be confirmed as poliomyelitis Furthermore, from a study of an outbreak in rural Connecticut, they concluded that the spread was connected with a particular river, and river epidemics in Sweden and Germany have been described by Kling Paul and Trask, therefore, carried out extensive tests for the virus in sewage From 66 samples, of which 13 gave unsatisfactory results, they isolated the virus at least 6 times, representing four samples of sewage from two different sites, one of which was the sewer pipe of an isolation hospital where cases of the disease were being nursed Two other points were established (1) that the total content of the virus in sewage may be large, and in this connexion they record in a footnote that monkeys can be infected by nasal instillation of unetherised fæces, and (2) that the virus is stable enough to be carried in sewage for at least an eighth of a mile From these findings Paul and Trask are cautious in drawing any conclusions They agree that there seems good evidence for the spread of poliomyelitis by direct contact, but they think there may be other channels including contaminated food, milk and water, and they direct attention particularly to the part which polluted watercourses may play in spreading the infection The epidemiological puzzle of poliomyelitis is still far from being solved, but perhaps we are beginning to find an explanation for its unusual seasonal distribution

MORE FAMILY BUDGETS

CONTINUING its analysis of the weekly budgets collected in 1937–38 the Ministry of Labour now gives a picture of the expenditure of the average agricultural worker, dietary studies of whom have been far less frequent than of his urban counterpart[3] The average size of the 1491 families contributing to the study is, rather unexpectedly, virtually the same as in the industrial households previously reported[4]—namely, 3 79 against 3 77 Their mean weekly expenditure is, however, substantially less, *57s 4d* as compared with *85s* The cost of housing in rural districts (rent, rates, water charges, &c) is naturally lower, *4s 9d* per week against *10s 10d*, though whether effectively less in relation to the amenities the family obtains for it is another matter —for instance, the urban household spends *2s 5¼d* a week on gas and electricity and the rural only *7¼d*, for they cannot spend on what is not there On clothing and footwear the average rural expenditure is *5s 3d* a week, the urban *8s 1d*, the former has the obvious advantage of a smaller expenditure on travelling and, as the returns show, the more doubtful advantages of a lower outlay on tobacco, newspapers, entertainments and doctors A greater proportion of the income has, of course, to go to food on which the average rural family spends *27s 9d*, or 48% of the total, against the urban family's *34s 1d*, or 40% The comparison, however, excludes allowances of food from employers or grown by the household, and this clearly much reduces the value of the comparisons one would like to make between urba and rural diets For example, from an early study o the diets of rural workers in Essex,[5] Bradford Hill concluded that at that date (1923) the rural diet was barel sufficient, though it compared favourably in som respects with urban diets of families with larger incomes owing to the home produce It was, however, les varied, with a substantially smaller amount of meat an considerably more bread and flour The Ministry o Labour's budgets show the same tendency, but th differences are narrow For instance, the averag agricultural household spent *4s 2d* weekly on bread an flour and the industrial household *3s 6¼d*, on mea (including poultry, rabbits, bacon, ham, &c) the forme spent *7s 2d* and the latter *8s 1¼d*, while the figures fo sugar are *1s 3½d* rural and *1s 0½d* urban The mai items of food provided by employers are milk, potatoes and (in Scotland) oatmeal, while home produce la mainly in potatoes, cabbages, and eggs, all importan items in a good diet From the figures available i should be possible to build up a broad compariso between the diets of the urban and rural groups, and even though it be not complete it would be of interest

TERMINOLOGICAL EXACTITUDE

SPEECH, that late acquirement of the tool using animal, has little precision as yet Even our most careful statements convey but a rough meaning, and scientific terms—especially psychological terms—have often as many interpretations as interpreters Some day our speech may become as exact as mathematics, and in an attempt, perhaps, to hasten that good time the brain injuries committee of the Medical Research Council have published a glossary of psychological terms commonly used in head injury Their aim has been to achieve greater uniformity in case-notes and the definitions set out are already in use at the special centres for the treatment of head-injuries, if they were generally adopted in the medical services the clinician attending a transferred patient would derive an accurate idea of his state from his notes Only sixteen terms are defined coma, semicoma, confusion and delirium, traumatic stupor and automatism, concussion, traumatic dementia, intellectual impairment and personality disorder, malingering and hysteria, insight, judgment and comprehension, and amnesia The committee point out that the definitions are arbitrary and may not be universally acceptable, but rightly insist that to avoid further ambiguity they should be accepted and used After all, it matters little what a word means provided we all agree on its meaning If we need new terms we can always invent them neologisms are not the prerogative of the insane The other M R C committees might well follow suit by defining their own terms, and in the end we may get what we badly need—a good English glossary of scientific terms There are some excellent American dictionaries, but they show troublesome divergences in spelling and sense from accepted standards over here There would be an all-round gain if English speaking scientific people could speak and write the same language, and a joint Anglo-American committee on terminology is needed to bridge the gaps

SIR WILLIAM SMYLY died at his home in co Dublin on March 19 at the age of 90 Born and bred in the medical tradition and one of the pioneer obstetricians he played a leading rôle in Irish medical life a generation ago Master of the Rotunda Hospital 1889–96 he became president of nearly every group of gynæcologists in the Empire, and finally president of the Royal College of Physicians of Ireland His writings are to be found in all the systems of medicine of the period t everyone also recognises that certain people in tain circumstances are so ‘difficult’ that they ome ill as a result. This is undoubtedly happening a large scale now and neuropsychiatry is coming into own and developing a rapidly expanding vocabulary is clearly desirable that the unfortunate neurotic uld not be allowed to think that he has an organic ease or injury, and the abandonment of the label hell shock” formerly pinned on him is an excellent ve. It is also reasonable that only those doctors o possess the necessary amount of patience should l with them. Presumably all neuropsychiatrists ve this amount (one would like to forget the few one ows have not) and are therefore the best men for the But I can only wonder what else this spate of pers means. Perhaps the writers are themselves acting with abnormal violence to their changed ironment—or do neuropsychiatrists never do this?

Returning to the analogy to the second law of motion, e ability to hold on to the changed direction and locity might serve as a definition of “guts.” Naturally person exhibiting this is aware of his altered condition d neither welcomes it nor is indifferent to it. He cepts the situation and having accepted it produces internal stimuli of disruption and resists any external es. The longer the changed circumstances continue e greater the degree of staying power, stamina or guts.” Explosive disruptive influences from within e most likely to occur in either the very poorly or the ghly civilised groups. In the former a mass phenomenon ily readily appears interrupting the activity of e moment. In the latter, where the ability of intellectual perception is well cultivated, the individual is sceptible to influences of change because he possesses critical faculty and is able to appreciate the several spects of any problem. Ordinarily the term panic is sed to describe the former reaction; the latter is more omplex and is difficult to label in a word. But on these rms the disruption of the Polish and French peoples this war is understandable, and that of the Russians nd Germans in the last. On these terms too will be ttled the present conflict of the British and German aces and their plans for the future welfare of the ilised world. It is thus important to provide conditions which will prolong our own ability to continue long our present course. Therefore it is essential hile inducing an acceptance of the present temporary nditions in the minds of the majority to see that this s firmly based on ideas and emotions which connote omething more permanent for, being (we hope) a highly ilised people we may be given unnecessary scope for he exercise of our critical faculty. Actually this should ot be difficult, for our opponents have from this point f view behaved in a grotesquely stupid manner, and ave themselves provided many stimuli which would ormally keep us firmly on our changed course in pposition to them. The history of the last year has hown that our propaganda folk are rather lacking imagination in the use of this material. In fact, there has been a noticeable tendency to avoid any statement which in any way touches on essential sociological ideas, and it is hardly unpatriotic to note that there are many who are disturbed by this (to them) fundamental omission. These people naturally include a number of the more intelligent and trained minds, and they require for their stability in new and difficult conditions more than has as yet been vouchsafed. Our own profession is an excellent example. Never in any two years since the dawn of civilised medicine has so much been thought, written and read about the practice of the profession and the organisation of its future services. This corresponds politically with war aims and the executive direction of the war. The secret formation and the composition of the Medical Planning Commission came to many doctors with the same shock that the recent banning of certain artists by the B B C came to many of the lay population. A conflict is recognisable which can be the origin of disruptive forces.

* * *

There are many individuals who have had the curiosity (or intellectual activity) to study social trends and events of the last few years, who consequently believe that drastic modifications in the conditions of existence are necessary, but who lack the inner explosiveness to alter their own course or velocity. An easy label—intelligentsia or highbrow—can be pinned on these folk, but their position is readily understood, because their lives are generally untouched, or at any rate only very lightly touched by the passage of events. Just occasionally their material existence is improved by the war. It should be different where people are forcibly deflected from their paths, especially when this is suddenly and violently performed. Some degree of disorientation would be expected. I was surprised to find that among my new associates this form of vertigo was surprisingly absent. Moreover, they were largely unconscious that they had undergone an experience which might have resulted in instability; they had suffered a change of direction but no alteration in velocity. This cannot be accepted simply as a natural phenomenon and dismissed from the mind. There must be reasons for such behaviour. The book of Job supplies one—faith. A number, although I suspect a small one, are religiously convinced of the justice of the cause. Others of us are convinced of the ability and honesty of our new leaders. But presumably a similar emotion activates the German people. Dynamically it is a stable condition only if the leaders really possess this ability and honesty. Religion is an extroversion of an internal emotion, and as such is generally unshaken until replaced by some even more powerful emotion. It is a universally distributed attitude of mind. The demand for leadership is also pretty universal, but is a less powerful instinct because it depends on demonstrable qualities such as ability and honesty. Fluctuations of price on the pre-war Stock Exchange readily demonstrate how unstable this emotion can be. Its foundations are inherently insecure and perhaps not enough attention has been given to this fact by those responsible for the direction of our war-time activities.

* * *

Whatever my lot may be after this war one job I will never take on is that of a billeting officer. Even on a small scale it has caused me more worry and inconvenience than seemed humanly possible. It was probably asking for trouble to try to plant my particular brand of “billetees,” medical students, on my particular brand of “billeters,” middle-aged or elderly inhabitants of suburbia transported to the Home Counties. The problem of how to begin was met by persuading my wife to ask a friend whether she knew of any of her friends who would like to have a particularly nice type of medical student as a billetee. Aided by the fortunate coincidence of an influx of official evacuees from London, the response was overwhelming. Even a medical student was considered preferable to the unknown quality of official evacuees, and in the end my main trouble was explaining to importunate potential billeters, always on the telephone, that there really was a limit to the number of students we could supply in any one area, but (and this proviso was the only way, I found, of ending the conversation) should by any chance any further students arrive I would be only too pleased to let the lady have them. The story, however, was very different at the beginning of the next term when a fresh batch of men had to be accommodated. In the interval the official billeting problem had become much less acute. This time it was either a blank refusal, or the billeter had been ordered a rest by her doctor, or the domestic servant problem had become hopelessly acute. So the search had to be begun all over again and fresh fields sought where medical students and their ways were still unknown. Inquiries, usually carried out surreptitiously by my wife, as to how the students behaved produced the startling reply that they were not “house-trained.” In my low mind this phenomenon was associated with the alvine habits of infants and dogs, but here it included habits of leaving clothes all over the bedroom floor and using hair grease which spoilt the pillow-cases. The most indignant of all the landladies complained that her lad from the north, having been invited to partake of his host’s beer at dinner on his first night, took it for granted that he would have the same privilege every night. Why a lady of some fifty years did not take the obvious step of pointing out the error of his ways at once instead of storing up her indignation for a term and then letting it loose on my unfortunate wife I have never been able to make out. It has all been an not be used, the best application is some form of soap flakes) No violent scrubbing or scraping should be used, nor should antiseptic solutions or spirit be employed If the burn area is impregnated with oil or grease, ether soap is of value for cleansing Extensive burns should never be fully exposed at one time, owing to the risk of increasing shock by loss of body heat a limited area only should be exposed for treatment which should be completed before the next area is dealt with Loss of heat is especially marked when ether soap is used After the cleansing process has been completed, the burn surface and the skin around should be dried and the burn surface should be lightly dusted with sulphanilamide powder, a coagulant is then applied except in the areas mentioned below

Coagulant applications—The following solutions are the most suitable as they act quickly and require no special apparatus silver nitrate, 10%, tannic acid 10%, silver nitrate, 10% and tannic acid, 5%, used alternately, triple dye (one formula in common use is equal parts of gentian violet, 1 in 400, brilliant green, 1 in 400, and neutral acriflavine, 1 in 1000)

The application is best made by the use of a large gauze mop, no dressings are required over the coagulated area, but it is advisable to cover the part with a sterile towel after the coagulum is dry The edges of the area and any cracks that may develop on the surface should be dusted daily with sulphanilamide powder In whatever way coagulation is effected the coagulum must cover the whole area and a good margin of unaffected skin around, and must be firm and dry or, else the effect of the treatment is lost as the patient will still lose fluid from the burn area

No coagulant of any kind should be used on the face the hands and wrists, and the feet Circumferential tanning of a limb should be avoided if possible, and if carried out the peripheral pulse must be carefully watched for the first 48 hours Coagulants tend to contract on drying, and there is a risk of dangerous constriction of vessels or distortion of tissues (e g, the fingers and eyelids) as this occurs In addition to the solutions given above, tannic-acid jelly and gentian violet jelly are coagulants

Treatment of burns in areas which should not be tanned—After cleansing, the surface of the burn area is dried and dusted with sulphanilamide powder A tulle gras dressing is then applied, and this in turn is covered by 6–8 layers of gauze wrung out in warm normal saline The gauze must be kept moist by warm saline being dripped on it from time to time, and on no account must it be allowed to become dry The tulle gras will enable the gauze dressings to be removed without causing pain or injury to the burn surface, provided they are kept moist, as a rule it is advisable for the first few days to change the gauze every 3–4 hours, the tulle gras being left undisturbed during this process Twice a day at first, and subsequently, according to the progress of the case, once a day, the tulle gras dressing is changed, where it is possible to immerse the affected part in a bath, the tulle gras dressing is allowed to float off, which it does readily In the case of the face or other parts for which a bath cannot be used, a gentle stream of saline greatly assists in the removal which should be painless and not associated with bleeding Where baths are used the limb can remain immersed for half an hour or more, the saline being kept warm throughout Before applying a fresh dressing the unburned surface of the limb is dried, and the burn area dusted with sulphanilamide powder

Tulle gras, originally a French preparation, may be prepared in the following way Curtain net, with a mesh of 2 mm, is cut into pieces 9 cm square, these are placed in a tin box of slightly larger size The box is then filled with a mixture containing soft paraffin, 96 g, balsam of Peru, 2 g, sufficient being used to impregnate and cover the material completely after sterilisation by heat in an autoclave The French preparation contained also halibut oil, but the value of this when applied locally is doubtful, and it can be omitted

Dressings must be carried out with full aseptic technique, and special care must be taken to ensure the surgical cleanliness of the arm and leg baths An oil silk or jaconet bag or cover is of value in keeping the gauze moist in the case of the arms and legs, both while the patient is in bed and during transport Where burns of the face are treated by saline packs, a jaconet bib assists in keeping the patient and the bed dry It is made as follows

Take a piece of stout wire and bend it into an oval about 14 in in its long diameter and about 8 in in its short diameter A piece of jaconet is then cut, of sufficient size to form a deep basin when its edges are sewn to the wire hoop Towards one end of the jaconet basin cut a hole large enough to go over the patient's head, the edges of this hole should be turned over and sewn so that a tape can be threaded through the channel so formed On tightening the tape the opening can be made to fit round the neck At the other end of the basin a small hole is made into which a tube for drainage can be tied

All cases of severe burns likely to be followed by loss of function or disfigurement, or to require extensive grafting, should be transferred to a burn centre as soon as they are fit to travel

---

In England Now

A Running Commentary by Peripatetic Correspondents

AN abrupt translation in my existence recently occurred and I found myself in an entirely strange and remote part of the country, living and working with a fresh group of people In London it is so customary to hear free discussion of the war, of changes in social conditions caused by it, of motives guiding the events leading up to it, that I became conscious of a gap in mental activity when I found that nothing of this sort happened in my new company I thought it odd that my associates, most of whom were middle-aged (many had served in the last war), were so uninterested in the reasons for their changed circumstances and for the sudden transition in their lives It would seem no light matter to relinquish tasks on which one has been engaged for years, a home one has painstakingly constructed for a family diligently nurtured, and to find oneself doing something entirely different in scope and aims in the company of strangers equally quaintly employed In many cases, as I have mentioned, this was happening for the second time In Newton's laws of motion is the postulate that matter moves in a straight line with uniform velocity until acted upon by some external force when it changes either its velocity or its direction and often both Man seems to answer to the same mathematical theorem and seems generally to show as little inclination to effect any alteration in his new properties This might be due to indifference or even a welcome to the changed circumstances It is the fashion nowadays, as every medical periodical is a witness, to ascribe people's reactions—their resistance to change of velocity and direction—to psychological conflicts and inability or ability to overcome them All these learned articles boil down to the original Kraepelinian postulates that abnormal behaviour is merely an exaggeration of a normal behaviour response, and is not a different response Each psychiatrist or psychoanalyst says that as a result of his study of x cases of mental disturbance or breakdown he has found that each case has over-reacted to his changed circumstances along lines which could be foretold from a previous study of his past behaviour Vulgarly, so what? Surely it is a commonplace that we each as individuals react in a similar way to similar stimuli—any poker player would tell a psychologist this! And it is not very clear where these learnedly written articles with their queer technique of verbal description are leading us They all seem to end in the same way, rather vaguely saying that appropriate treatment in highly trained surroundings is sometimes successful—and sometimes isn't Anyhow, by definition, there is no reason why these patients should be "cured" as they are merely being themselves I also cannot make out why it is necessary always to stress that the staff are highly trained merely because they are able to be reasonably patient and intelligent with neurotic men and women, and, since optimistic suggestion should be part of the treatment of any case, why is it always necessary to state that the staff must be highly trained before they can possess this piece of ordinary nursing technique? Surely sympathy, a good ordinary word to describe such an attitude towards the sick, is an essential quality of all who practise medicine or nursing It is a matter of common knowledge, lay and medical, that certain people are "difficult" when they are ill, and I think abnormal times it was impossible to adopt the recommendations of Lord Perry's Committee The chief recommendation was that the margin allowed for the distribution of milk should be drastically curtailed in the interests of the consumer The average consumption of milk was one gallon a family each week, and this would mean a saving to each family of *4d* a week In spite of war conditions the milk trade had rendered good public service sometimes at a financial loss, and they had produced considerable evidence that they would find it impossible to continue business under the margins suggested by the Perry Report Lord WOOLTON warned the country it would be difficult to maintain our milk production at its present level Under the National Milk Scheme introduced last July 10,000,000 gallons were distributed to 2,800,000 people About a third received the milk free and the others paid *2d* per pint He hoped to maintain an unrestricted supply to nursing and expectant mothers and young children, and to maintain supplies to hospitals and invalids But he must use the balance of our milk-supplies for the greatest need of the nation, and he had decided to restrict the consumption of milk by the ordinary man and woman He was asking dairymen to reduce their domestic sales from the middle of April by a seventh The milk saved would be used to increase the production of cheese and condensed milk, which we should certainly need next winter Bakers and flour confectioners would have to dispense with use of milk, and the ban on the use of fresh cream and the manufacture of synthetic cream and ice-cream would be continued This summer we should probably have more milk than we need, and this surplus must be used for the best interests of the nation

Remand Homes

Mr O PEAKE, under secretary to the Home Office, informed the House of Commons that there was an increase in the number of children and young people brought before the juvenile courts It was hoped that the pressure on remand homes and approved schools caused by this abnormal increase in juvenile crime would soon be relieved [1] A conference would shortly be called to consider how best to provide suitable accommodation

QUESTION TIME

N H I Income Limit

Sir ROBERT YOUNG asked the Minister of Health whether he was aware of the difficulties arising, or likely to arise, out of the failure to increase the income limit for compulsory health insurance to £420 a year, as had been done for compulsory unemployment insurance, as many insured persons owing to transference to administrative and similar positions, or from the receipt of overtime payments were being forced to become voluntary contributors, entailing the loss of medical benefit and the payment of all contributions due under such conditions, and as many of these insured persons were likely again to become ordinary workers with less than £250 per annum, so having to become compulsorily insured and causing difficulties for them and much trouble and expense for approved societies, he would raise the income limit at an early date —Mr E. BROWN replied The Secretary of State for Scotland and I have this question under consideration and hope to be able to make a statement shortly

Medical Publishers

Sir ERNEST GRAHAM LITTLE asked the Minister of Labour whether he would give consideration, in revising the schedule of reserved occupations, to the necessity of retaining a sufficient number of employees of firms publishing medical and nursing books, a category in which fresh publications were demanded by the continuous advances in medicine and nursing —Mr GEORGE TOMLINSON, parliamentary secretary to the Ministry of Labour, replied I am advised that it would not be practicable to place such publishing firms in a special category If in any case it is regarded as important to retain the services of a particular individual, application for deferment may be made in the usual manner

Health of Apprentices

Mr DAVID ADAMS asked the President of the Board of Education whether, in conjunction with his experiments in the physical training of apprentices during their working hours, and the effects of this upon their output, he would, in coöperation with the Ministry of Food, experiment also with diets in order to ascertain effects upon output and health —Mr HERWALD RAMSBOTHAM replied I will certainly bear the suggestion in mind

Batteries for Hearing-aids

In reply to a question Captain C WATERHOUSE said There have been difficulties, due to increasingly heavy service demands for miniature cells The problem of arranging for the use of other types of cell in hearing aids is being examined in consultation with the manufacturers, and meanwhile supplies of miniature cells are being released

Diphtheria Inoculation in Edinburgh

In answer to a question Mr T JOHNSTON gave the following figures for diphtheria inoculation in Edinburgh —

	1938	1939	1940
Approx no of children immunised	31,000	33,000	34,000
Immunised children who contracted diphtheria	31	23	9
Fatal cases among these children	1	0	0

Public Health

From the Annual Reports

HARROW

Dr Caryl Thomas starts his report with a dissertation on matters of importance in public-health administration, including milk for mothers and children, food and drugs, and housing Dr Thomas is a barrister-at-law and an epidemiologist, a combination of particular value in discussing the various points he raises In spite of the numerous acts of Parliament, since the Public Health Act of 1875, which deal with the housing of the working classes nobody is satisfied with the policy as it stood at the outbreak of war, and many medical officers, not having had a legal training, cannot find their way through the mass of legislation which to them is more confusing than helpful Dr Thomas calls attention to some of the anomalies which confront us, one, which is outstanding, is that building by-laws will allow houses to be built which promptly become a nuisance The local authority must pass plans which conform to the by-laws even though their officers may point out that the houses when built must speedily become unfit for habitation Dr Thomas tells of a clearance scheme which after months of hard work came to an inquiry The council having considered a slum area from all points of view decided that clearance was the only feasible procedure After weeks of expensive quibbling, the findings of the inquiry were that five properties were to be demolished, but the outbreak of war caused even this slight mitigation of a public disgrace to be shelved

The urban district of Harrow covers 12,558 acres and is densely populated (190 200 inhabitants) The birth-rate shows that it is fertile, the low death-rate that it is healthy, and the population is young The stillbirth-rate was 31 and infantile mortality-rate 38 5 both low and evidence of good midwifery and child welfare The incidence of diphtheria was low—85 notifications in 31 of which the diagnosis was withdrawn—but the fatality reached the very high rate of 19% Dr Thomas notes that when diphtheria is low in prevalence the fatality is high because when the disease is out of mind parents are less suspicious of sore throats in their children, and delay seeking medical advice This is undoubtedly so, but there may be other reasons, a high fatality with a low incidence occurs in other infectious diseases for which we have no specific remedies

CHESTER

Dr J W Lobban's report contains much statistical information but no commentaries, though there were several features in the town's health record which call for explanation We are told that the water-supply is abundant and that the standard of purity obtained has been remarkably good The water is taken from the river Dee and purified, the criterion of purity being absence of *B coli* in 100 c cm The details of chemical analyses for each month of the year are given and these show unusual variations, we are not told from what part

---

arch 22, 1941, p 393

interesting study of human nature—the reaction of the varying types of individuals both old and young, and the age-long inability of the average person to put himself or herself in someone else's shoes But I shall have no objection to a rapid shortening of the period of study

* * *

It has been suggested that the majority of the B M A Planning Commission ought to be under 45 years of age because it is the younger men who will have to do the work of the profession in the future It seems to be thought that on account of their age those over 45 are unlikely to plan the kind of profession in which the younger men will want to work Though the respective rôles of youth and age in Parliament and the Cabinet as well as in the councils of medicine might well be considered by physiologists and psychologists as part of our planning for the future, the matter is surely not as simple as that For it is certain that those under 45 will gradually become fogies as old as those they now criticise, and if age determines outlook they will then like the sort of profession that old fogies like now, and not the sort designed by themselves when they were under 45 Moreover, since it is the privilege of youth to disagree with age, the next generation of under 45s will certainly disapprove of the profession planned by those old fogies who by that time will be 50, 60 and 70 It seems, then, that a profession planned to conform to the political fashion of a current age-group is unlikely to satisfy anybody for long

The criticism that public-health interests are inadequately represented on the commission sends one looking for a reason, which is, I think, that practising doctors, however notable the exceptions, are rarely interested in public health As citizens they approve in general of someone doing something to improve public health, but the type of mind which is interested in therapeutics is not often interested in preventive medicine Surgeons have contributed nothing to the prevention of appendicitis, and cardiologists show no signs of contributing anything to the discovery of the ætiology of coronary thrombosis Nor should this be regarded as a reproach to them The truth is that the therapists are concerned with, and interested in, end-results which are remote in time and differ in nature from their causes The causes need to be studied by investigators with entirely different training and interests Public health is still suffering from being regarded as a poor relation of therapeutics There should be a Ministry of Disease concerned with therapeutics and a Ministry of Health concerned with prevention, with, of course, liaison officers between them The Ministry of Health, which, incidentally, would have a large staff of architects and sociologists and other laymen as well as medical research workers, could then get on with its job of abolishing the Ministry of Disease And clinicians, even in war-time, would not have to work in a medical service designed by the Ministry of Health

* * *

Breakfast in bed is a much overrated pastime There are some who adore it, others who detest it, but for the large majority it is merely a great nuisance There are times when one is driven to take breakfast in bed whichever class one belongs to, and the necessary technique requires careful study beforehand, for it is difficult to work out the various possibilities early in the morning when just awakened Shall one lie on one side, balancing on one elbow, and attempt to shovel food and drink with the other hand from a tray on the bedside table into a mouth which seems always aslant? Shall one try to sit up, with the tray balanced precariously on the knees, and guide the food over a wide expanse of blanket and sheet, with all the hazards of the slip betwixt cup and lip? In either case one is driven to think of the ancients who appeared to derive pleasure from reclining at meat The correct technique, I am told, is to sit bolt upright, with the pillows arranged vertically against the head of the bed, and get the tray tucked well into one's lap, but it is still a long way from the plate to the mouth There is always the fear, too, that one will be left thus for some time, while the rest of the family finish their breakfast at leisure in the dining-room, and in the meantime one's chest and arms will get frozen Only the real addicts possess one of those decorative trays with legs that help to bring the food nearer to the mouth and can more easily be disposed of when the meal is completed Eve then the hazards of the game are innumerable, whe I was a boy my most unpleasant aunt—one of th psychopathic tenth I see she was now—had one and th front legs collapsed spilling hot coffee all over he How we did laugh

Parliament

THE serious effects which the Government's ne proposals for the registration of women for war wor may have on the public-health services were emphasise in the debate in the Commons on the third reading c the Consolidated Fund Bill Miss IRENE WARD urge the imperative need for maintaining the efficiency o the nursing services, and for securing proper treatmen for the personnel Nurses' professional organisation were anxious that the new division of nursing in th Ministry of Health should be in the charge of thos qualified and experienced in nursing She also aske for an official announcement on nurses' superannuation What happened to the nurses after the last war mus never happen again Viscountess DAVIDSON said th the effect of the Minister of Labour's broadcast had bee disquieting Many people believed that compulsio would be applied immediately after registration A one civilian hospital of 1500 beds, dealing with old wome removed from hospitals in the large towns, many of th domestic servants had left within 24 hours of Mr Bevin' speech to enlist in one of the armed forces Lad DAVIDSON also asked that mothers with young childre should not be conscripted

Dr EDITH SUMMERSKILL feared that, after a tremen dous amount of propaganda had been done to teac women how to feed their children properly, the Govern ment were now going to hand those children over t unsuitable people who would act as "minders." Minders she said, should only supplement and not be a substitut for day-nurseries The Midwives Institute was askin that the Minister of Health should make it an offenc for a woman to be employed during the four week preceding her confinement Dr SUMMERSKILL suggeste that nursing mothers employed on war work should b allowed time to feed their babies while at work Mis F HORSBRUGH, parliamentary secretary to the Ministr of Health, denied that it was the intention of th Government that people engaged in essential work, suc as work in hospitals, should leave their employment Every effort had been made to add to the numbe of day-nurseries, but they did not meet all the needs and this had led to the system of leaving children in th care of minders The present proposal was to registe these minders so that the health visitors could satisf themselves that they were suitable Miss HORSBRUG said that at present the nursing staff in the E M S hospitals numbered 75,000, of whom 17,000 were i the Civil Nursing Reserve The fever hospitals an some of the special hospitals were not getting sufficien recruits, and they wanted nurses who would go anywher and nurse anyone There were difficulties about nurses superannuation which it would be almost impossible t overcome in war-time, but a further increase of pay wa being made to members of the Civil Nursing Reserve s that they might pay their share of superannuation Under the new scheme they hoped to form a centra register for those who would come into the nursin profession for the duration of the war, or who wer looking forward to work in the nursing profession later They would fix a minimum rate of salary during th war which the hospitals who took probationers from th register would be required to pay This scheme did no go as far as was suggested by the Athlone Committee but it was a step in the right direction

Mr R ASSHETON, parliamentary secretary to th Ministry of Labour, made it clear that if any woma was directed to work to which she objected she would have the right to appeal Women would not be medicall examined on registration, but they could produce medica evidence of disability, on which the Ministry would als be entitled to obtain an independent medical opinion

Surplus Milk

Last week Lord WOOLTON announced in the House o Lords that the Government had decided that in the in the psychological diploma is oddly reminiscent of a dictator's idea of coöperation with a small state or a boa constrictor's hope of coöperation with a lamb. In all three cases there is the same engaging naïvete

Group Captain Symonds is ungenerously in error in accusing the psychotherapist of trying to elbow his way unnecessarily into the sphere of mental disorder The psychotherapist, though not always himself aware of it is in this sphere the authentic voice of that other half of man which, though it may be driven into the wilderness of medical disrepute, will not and cannot be completely silenced

Harley Street, W 1 ALAN McGLASHAN

SIR,—Among various circles of psychiatrists Dr Symonds's presidential address must have had the effect of a landmine Were it not for the fact that acute controversy on general subjects is now the height of bad form we might expect bitter protests from those students of the mind who prefer to ignore the activities of its cerebral basis As it is, Dr Symonds's materialist bomb will no doubt be treated as an unfortunate brick unworthy of notice. Nevertheless the address marks the beginning of the end of "pure" psychiatry particularly of that section which treats psycho-analysis as the core of all wisdom. Pigeon-hole methods of classifying mental conditions likewise receive notice to quit in an address which forsakes "fixed clinical syndromes" for those manifold and mutable abnormal reactions that express a disordered mind In the subject of mental disorder, brain activity and its abnormal disturbances are now being studied from that materialist point of view which recognises the brain to be the physical basis of mind

From this point of view, every case of mental disorder is part of a dynamic "eternal triangle" consisting of the brain and body as a whole, of the mind which is dependent on the brain, and of that external environment which the mind reflects and reacts to through the activities of the nervous system The treatment of mental disorder will therefore embrace not only a consideration of the relationship between the mind and the external environment, but also of the various cerebral activities which relate the individual to the environment It is an axiom that all mental disorder must be based on some corresponding cerebral disorder and clinical science now begins to utilise in practice this principle of modern materialism

At the same time clinicians will not fall into the old error of regarding the external environment as unalterable and "normal," whatever its character, to which the patient must necessarily adapt himself like a prisoner in a cell. War, hunger and social disorganisation give an external environment to which a great many individuals are unable or unwilling to adapt themselves indefinitely, and if clinicians have only "adaptation" to urge upon patients about to leave the mental hospitals the sheep if not the goats among them will surely bolt back to the security of padded cells But in all seriousness, the sociological side of the question cannot be neglected, and the bare doctrine of adaptation to the environment whatever its character is one which has nothing in common with a scientific outlook on society Only a devotee of the blitzkrieg can present today's environment as a state of affairs to which men and women must merely adapt themselves indefinitely Between the abnormalities of psychotics and the "normalities" of modern society there is a closer connexion than one might gather from most textbooks of psychiatry—a connexion not to be disposed of by the simplicities of convulsion therapy

Oxford R. L WORRALL

ANDROGENS IN GYNÆCOLOGY

SIR,—Your leading article of March 15 (p 351) remarks on the masculinising activity of testosterone and its propionate when given for various gynæcological disorders This unwanted action will undoubtedly dissuade many practitioners from availing themselves of an otherwise apparently harmless and effective therapeutic procedure In three of the four complaints mentioned (functional uterine hæmorrhage, dysmenorrhœa and chronic mastitis) the action of testosterone seems to depend on the direct antagonism which it possesses to endogenous œstrogens It has been shown (Emmens, C W and Bradshaw, T E. T *J Endocrinol* 1939, 1, 378) that androstenedione and androstanediol are as potent as testosterone in inhibiting the response of spayed mice to œstrone, yet possess only a fraction of its androgenic activity in mammals ($\frac{1}{6}$ and $\frac{1}{4}$ respectively) It might accordingly be worth while to give these compounds a clinical trial in such disorders, in the hope that they would be as efficient as testosterone in the desired direction, without the same tendency to produce masculinisation in effective doses The inhibitory effect of testosterone on lactation may be due to an indirect action on the pituitary body, and there is no evidence that the other androgens mentioned would be as effective It might nevertheless be again worth while to put to direct test, by clinical trial the question whether one of the other androgens would not produce the desired effect without the undesired concomitant actions of testosterone

THE RIVER EMERGENCY SERVICE

SIR,—As the M O of an ambulance ship in the River Emergency Service I had recently been anxiously waiting for a relief M O to take on my duties, so that I could have seven days' leave still due to me from last year (we are magnanimously given two weeks in the year) At last he arrived and I was all set to get away as I thought. We introduced ourselves He has named me McCork in your journal (March 15, p 359), so I shall return the compliment and call him Bull, but of the Ferdinand instead of the John family He looked over the ambulance ship and wasn't impressed, as there was no private cabin for the M O He saw some V A.D nurses doing Thomas splint drill and, informing me that he hadn't seen a Thomas for twenty years, didn't believe in it and always used a Liston, he said he didn't think much of their efforts Having remained on board for fifteen minutes we went up to our billets He was very upset at the apparent lack of comforts and conveniences and said, "This is a dreadful place Your P.M O told me it was comfortable I must telephone him immediately. I'll just stay two days until you get away, and then clear out" When I told him that I would not leave knowing that he wasn't going to stay until I returned, he said, ' Well, I'll go straight away and departed bag and baggage having been with us exactly half an hour It was with mixed feelings that I watched him jump on a bus, I felt depressed as I saw my week's visit to my family vanishing into the future, but glad that I wasn't leaving the sisters V A D 's and stretcher-bearers (the ambulance officer who is an Ulsterman is able to take care of himself)—whom I have come to regard with some affection, having seen them stand up to five months of the blitz in this dreary dockland—to his mercies Perhaps it was as well that he left the docks and the uncomfortable billets to the "Neutral" and went back to sniff his crocuses and tomasinianus

McCORK

SIR,—Now that one of your peripatetic correspondents has concluded his extremely brief experiment with time and with the Thames and has fled back to his garden perhaps you will allow one of the medical officers who has been with the River Emergency Service for many months to reply to some of his strictures

The giving of lectures, which are more like the chats one used to give to one's clinical clerks or surgical dressers, and the practices, are real and of value The "comfortable billets" are real no longer, for they have mostly been bombed out of existence Had our critic been with us during the early autumn I doubt if he would have written so lightly of a "blitz on the river Trying to rescue people from burning wharves, getting a small peace-time pleasure steamer alongside flaming barges whilst avoiding those that had broken adrift (reminding one of heroes on their way to Valhalla), and trying in the heat and the smoke and the flame to stop pain and stay hæmorrhage has perhaps little in common with the *Crocus tomasinianus* even in its folded-up umbrella stage

When incendiaries rained on a certain dockyard and the sequela of H E was punctually noted, my sisters and nursing auxiliaries in their ' natty uniforms " (what ought they to wear—crinolines or gardening aprons ?) put out dozens of burning bombs and by so doing saved of the system the samples were taken, but these twelve analyses suggest that the water is poor and subject to frequent high pollutions Chester is a *small town of only* 4142 acres and 44,280 inhabitants, or nearly 11 persons per acre *Its birth-rate in 1939 was* 15 6 , death-rate 13 8 , infantile mortality 77 3 and maternal mortality 5 4 There were 37 deaths from all tuberculosis, giving a mortality-rate of 0 84 based on the population of 45,090—the number given by the Registrar General for estimating death-rates This is not a good health record for 1939 The endemic infectious diseases were not particularly troublesome in the year, the only one calling for comment was diphtheria with 135 notifications and 10 deaths

EXETER

Exeter is another small city, but its population of 70,000 being more than half as large again as that of Chester gives it a density of nearly 17 to the acre Most of our older cities, though not seriously overcrowded, are cramped, retaining some of the pattern of the fortified walled cities of medieval times Modern conditions would be served better if we cleared the centres of our cities and dispersed the population in the peripheries At present the enemy is doing the former for us, though hardly with discrimination , but whether we shall seize the opportunity to do our own part remains to be seen

Of the 212 persons on the blind register of Exeter at the end of 1939 all but one were over 50 years of age Owing to the Blind Persons Act, we have nearly complete records of the prevalence of blindness, and these show strikingly how prevention has reduced this calamity It is unfortunate that we have no such information of the deaf and do not know whether we have reduced deafness by preventive measures Dr G B Page's report indicates the extent to which tuberculosis is found in animals slaughtered for human consumption, not because the findings are exceptional at Exeter, but because they are average In carcases of cattle other than cows, 4 5% show evidence of tuberculosis Cows show definite lesions to the extent of 11 8%, and pigs 1 7% In calves tuberculosis is rare and in ovines a curiosity Of 34 tons 13 cwt of all foods condemned, 19 tons 5 cwt owed their condemnation to tuberculosis

Infectious Disease in England and Wales

WEEK ENDED MARCH 15

Notifications —The following cases of infectious disease were *notified* during the week smallpox, 0 , scarlet fever 1221 , whooping-cough, 3338 , diphtheria, 1033 , enteric fever, 28 , measles (excluding rubella), 15,056 , pneumonia (primary or influenzal), 1318 , puerperal pyrexia, 141 , cerebrospinal fever, 330 , poliomyelitis, 5 , polio-encephalitis, 2 , encephalitis lethargica, 7 , dysentery, 146 , ophthalmia neonatorum, 77 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on March 14 was 1837, including scarlet fever, 230 , diphtheria, 338 , measles, 451 , whooping-cough, 253 enteritis, 20 , chicken pox, 121 , erysipelas, 38 , mumps, 3 , poliomyelitis, 2 , dysentery, 26 , cerebrospinal fever, 85 , puerperal sepsis, 14 , enteric fevers, 4 , german measles, 9 , other diseases (non infectious), 135 , not yet diagnosed, 107

Deaths —In 126 great towns there was no death from smallpox, enteric fever or scarlet fever, 38 (2) from whooping-cough, 25 (1) from measles, 31 (0) from diphtheria, 36 (4) from diarrhœa and enteritis under 2 years, and 132 (15) from influenza The figures in parentheses are those for London itself

There were 7 deaths from whooping cough at Birmingham and 6 at Liverpool, and in the same week at Glasgow there were 15 Liverpool reported 5 fatal cases of diphtheria Bradford had 9 deaths from influenza, Birmingham 6, no other great town more than 4

The number of stillbirths notified during the week was 230 (corresponding to a rate of 42 per thousand total births) including 16 in London

INCIDENCE OF INFLUENZA

In the week ended March 15, 132 deaths were ascribed *to influenza in the great towns, 67 fewer than in the* previous week Of these deaths 6 8% were at ages under 25 and 54 54% at ages over 65 In the county of London 15 deaths were registered (13 in the previous week) The proportion of total deaths coming from the South-Eastern Area was 28 36% It would appear that the winter epidemic is now over

Letters to the Editor

HOSPITALS RADON CENTRE

SIR,—As the result of a generous gift from the British War Relief Society of New York further supplies of radon are now assured The gift was made to the British Hospitals Association, who have asked the Middlesex Hospital to administer it This new supply is intended for the use of hospitals throughout the country and no distinction will be made between requisitions for paying and non-paying patients It is hoped to increase the amount of radium in solution at this new centre when the demand warrants it

In the first instance it will be necessary to charge all hospitals for supplies of radon, and it has been decided to charge for it at the lowest basic rates obtaining at the *Medical Research Council radon centre—namely,* one shilling a millicurie—with a reduction to sixpence a millicurie for any quantity in excess of fifty millicuries the minimum charge for any radon requisition will be one guinea It is hoped that in the near future some arrangement will be possible whereby the burden of such payments may be lightened

Applications for radon may now be sent to the Hospitals Radon Centre, c/o Barton Lime Co , Barton in-the-Clay, Beds (telephone Hexton 210)

Middlesex Hospital, W 1 SIDNEY RUSS

THE NEUROLOGICAL APPROACH TO MENTAL DISORDER

SIR,—In your issue of March 15 Group Captain Symonds puts forward a brilliant contribution to the understanding of mental disorder The more's the pity it is vitiated by its unadmitted philosophic bias Distinguished members of our profession seem peculiarly apt to be unaware that any attitude, however well supported by observed *facts, rests inevitably* upon a philosophic basis , and their unawareness leads to much debate, marked equally by erudition and irrelevance Neuro-psychiatry *versus* medical psychology, as rival approaches to mental disorder, is one of the most fascinating—and profound—of these philosophic cleavages The mock-modest pretension of the scientist to have no time for philosophy does not absolve him from philosophic bias, but merely reveals his bias to be unconscious—or, as Group Captain Symonds may prefer to put it, forgotten This avoidable occurrence is, in fact, responsible for most of the needless arguments between intelligent men

What is here suggested is that Group Captain Symonds is right, demonstrably and irrefutably right, in his conclusions His world picture, in which his views on mental disorder have their inevitable setting, is consistent and as he says " makes sense " From his neuro-psychiatric fellows he should receive a magnificent endorsement of his opinions In the intelligent world as a whole, however, the unanimity might be less marked, possibly by some fifty per cent It is here suggested that the dissident half is not composed of merely ignorant and contumacious persons, but of persons whose world picture, in which their views on mental disorder have their inevitable setting, is *equally consistent, and* makes equal though very different sense It is finally suggested, that man is not *adequately expressed* in either world picture alone

The form-makers and the form-breakers—Abel and his brother Cain, the Aristotelians and the Platonists, the Apollonians and the Dionysians—these are the eternal prototypes through whose labours the world first moulds itself in lovely forms, then breaks through, painfully and often cruelly, to fresh beauty Always it was, and it will always be, the tragedy of the form-making mind striving to bring its well-loved order out of chaos, to see suddenly breaking from some unlooked-for covert Priapus with his imprudent gestures, Pan with his insulting pipes We are still bound by these prototypal limitations, and till the spanning mind comes forward no honest truce is possible What is, however, possible is for each to work in good-humoured self-awareness and equal rivalry The kind offer of cooperation on the basis that " there is no justification whatever for psychotherapy as a special branch of medicine," and with insistence on an increased relative importance for neurology

The unembroidered baldness of this note is determined in part by war conditions and also by the fact that the number of cases of the type is necessarily small

Bath A GUIRDHAM

ANURIA WITH CASTS

SIR,—In his account (*Lancet* March 15, p 345) of the pathological findings in nine women who had recently aborted, and who had died of suppression of urine, Dr Bratton says that the toxic process is not necessarily puerperal in origin , as these are not the post-mortem appearances of toxæmia of pregnancy, he might have gone further and said that this process is not puerperal in origin Mr Discombe and I have recently recorded (*Brit med J* 1940, 1, 525) the clinical and pathological notes of a patient who died with post-mortem findings identical to those which he has described, but the result of quinine poisoning In our case 5 04 g (76 grains) of the pure alkaloid had been taken by the mouth A search through the literature revealed only two similar instances, (Terplan, K L and Javert, C T *J Amer med Assoc* 1936, 106, 509 , and Raven, H M (*Brit med J* 1927 2, 59)

I hope it may not be too late for Dr Bratton to be able to trace whether quinine had been taken in his cases As they are all abortions the presumption is strong, and if so then the diagnosis of the disease process associated with his pathological findings is complete

Harley Street, W 1 C K VARTAN

TREATMENT OF ASPHYXIA NEONATORUM

SIR,—As you say, the methods of resuscitation outlined in your annotation of March 15 (p 355) are rather beyond the capacity of the general practitioner, and the proportion of babies requiring resuscitation (200 out of 1200) seems abnormally high Apparently the authors do not think that Barcroft's work on the initiation of respiration (*Lancet*, 1939, 2, 838, and see Leak, *Ibid*, p 1004) has much clinical bearing on this problem As a contribution to the treatment by the G P of those really bad cases which occasionally arise, I should like to record such a case which occurred about 15 months ago After a not very difficult forceps delivery the infant completely failed to respond to all my methods of resuscitation which included the administration of lobeline and ½ c cm of Cardiazol ephedrine, which latter I usually find more effective than lobeline itself After over 10 minutes' effort the baby seemed hopeless so I injected into the heart the remaining ½ c cm of cardiazol-ephedrine The effect was instantaneous the heart began to beat at once, respiration rapidly followed and within 2 minutes the baby was breathing almost normally No ill effects seemed to follow this treatment and the child is still alive and well Naturally, I do not recommend such a measure as a routine, but it may be a help to other practitioners who have not all the facilities of Russ and Strong in New Orleans, and anything which will avert the tragedy of a stillbirth is well worth while

Winsford, Cheshire W N LEAK

"WHOLEMEAL ENTHUSIASM"

SIR,—On reading the article under this heading in your issue of March 15 (p 370) I rubbed my eyes in amazement Can this be the same journal, I asked myself, which published as far back as Sept 14, 1912, a lengthy and generally favourable notice of Our Children's Health at Home and at School containing a report of the society's first guildhall school conference, and in recent years welcomed its offer to submit evidence to THE LANCET Commission on Nursing ? The Food Education Society had no connexion with Miss May Yates and the Bread and Food Reform League beyond cooperating in the effort to make wholewheat generally available It never advocated, as your reviewer suggests, "the exclusive use of wholemeal bread ' Nor is it committed to the views of speakers at its conferences, or of others figuring in Bread in Peace and War This society, which is said to be the oldest in the world for the education of the people in nutrition, has the support of the medical, dental, nursing and educational professions, and of social workers It is undogmatic and concerned with every aspect of dietetics, including food habits

London, N W 3 CHARLES E HECHT,
Hon Sec Food Education Society

"IN GRATITUDE TO MY MEDICAL COLLEAGUES"

SIR —I desire to acknowledge through your columns a donation of £50 from a doctor as a mark of appreciation of the kindness and consideration received from his medical colleagues during his wife's recent illness, which necessitated an extensive abdominal operation He adds " It is a very small return for all the kindness and skill that has been expended on my wife I wish my means allowed for a bigger cheque but I hope that I may be helping, through the Royal Medical Benevolent Fund, some unfortunate fellow medico or his dependants "

1, Balliol House, Manorfields,

Hon Treasurer, R M B F

INFECTION FROM DUST

SIR,—Considerable attention is being directed today towards floor dust as a source of cross-infection in hospital wards and elsewhere (Andrewes, C H *Lancet*, 1940, 2, 770), it being known that a number of organisms, particularly *Streptococcus pyogenes*, may remain there viable and at least potentially pathogenic for periods extending into weeks In the course of an extensive investigation into the preventive aspects of cross-infection now being made in this hospital on behalf of the War Office and in conjunction with the team of workers at the National Institute for Medical Research, Hampstead, we have assayed the streptococcal content of a number of dust samples from hospital wards Our complete data will be published later, but the results of these analyses are so striking that they deserve mention now to emphasise this aspect of such a commonplace as dust

During a mild outbreak of streptococcal sore throats and follicular tonsillitis in one ward a few weeks ago, all the dust swept up one morning was assayed, each sample being labelled as to its origin and treated separately The ward is an ordinary 26-bed hospital ward divided into two by a glass partition and door , the main corridor with the offices, &c and two single-bed isolation cubicles, runs off the ward at right angles At the end of this there is a large day-room which is only used by patients from the ward beneath, although the patients in this ward have to traverse it to reach their kitchen On the day in question there were 22 patients in the ward, all of whom except 3 exhibited *Strep pyogenes* (mainly type 6) in their throats One of the most severe cases (F) was isolated in a side ward The initial cases occurred nine days previously , the epidemic spread did not begin until four days before this experiment

The total weight of the dust was 29 06 g , which, for a morning sweeping, reflects a clean, well-kept ward The hæmolytic streptococci were distributed among the various samples as follows —

Ward (16 bed section)	16,261 000	Office	1,041,000
Ward (10 bed section)	23 323,000	Linen room	939 000
Cubicle 1 (F)	17 020 000	Staff day room	329 000
Cubicle 2 (non clinical case)	1 173 000	Day room (transit only) .	320,000
Surgery (E N T dept)	160,000	Entrance corridor (kitchen)	1 171,000
Main corridor	1 411,000	Annexe (w c 's, baths, &c)	38,745,000

The total number of hæmolytic streptococci swept up from the various parts of this ward on that particular morning was nearly 102,000,000

These experiments, apart from demonstrating the enormous numbers of bacteria which are present on the floor of an apparently clean ward, illustrate two important facts First, that very high bacterial concentrations may be met with even in small, single-bed isolation wards, and unless these are effectively dealt with they may represent a semi-permanent reservoir of infection for succeeding patients in the same ward Secondly, that the highest number of organisms is present, not in the dust of the ward, but in the dust of the ward annexe with its w c 's, lavatories and baths This observation confirms the work of Miles et al (*Brit med J* 1940, 2, 855, 895) on the rôle of baths in hospital cross-infections

If the organisms remained on the floor the risk of infection would be greatly reduced In ordinary wards, of course, without special floor treatment this is not so, and millions are re-projected into the air with each sweeping Parallel air counts during this work showed that while F's cubicle was being swept, 1 500,000 gentian violet the dockyard near their billet and so freed the fire brigade to attend to other fires

I have never met the "well-fed, smooth-spoken and pleasant" Dr McCork, as I have not served on an up-river ship, but if, as your correspondent avers, he comes from a neutral country all the more honour to him for joining us in the front line

All comparisons are invidious but I claim that if there was a front-line between the fall of Dunkirk and the start of the Wavell campaign it was the Thames Estuary, and from personal observation I can state that the members of the River Emergency Service—doctors, sisters, nurses, stretcher-bearers, and professional crews—behaved with a gallantry and efficiency that left me their humble admirer During latter weeks, when the longueurs of inactivity have been more pronounced, they have accepted their billet-less, bath-less, communal-sleeping fate with cheerfulness and dignity and so far as I know not one of them has scuttled back to his or her rabbit-hutch They are rightly proud of their record

R C H

SIR,—I feel that your peripatetic correspondent has done an injustice to medical officers, nurses and stretcher bearers who have given up comfortable jobs to join the River Emergency Service, many since the outbreak of war At the beginning many of the personnel slept and cooked for themselves on small steamers built for short pleasure trips, the hours on duty being 96 hours on and 48 hours off After some months good billets were gradually provided near the action stations of the ambulance ships As a result of enemy action six billets have been either demolished or badly damaged The personnel have shown great cheerfulness in putting up with a good deal of discomfort in an endeavour to continue to cover their sphere of action The billets to which your correspondent refers are a hospital ward, furnished with armchairs, the usual fires and very good comfortable beds The personnel consider them very good billets compared to some other stations more severely knocked about It is perhaps just as well that your correspondent returned to the care of his crocuses

D S GORDON,
P M O , Port of London Authority

A HUNDRED CASES OF BREECH PRESENTATION

SIR,—Drs Gairdner and Jackson gave figures of the fœtal mortality under the various forms of treatment adopted in each series of cases—i e , version, delivery per vaginam, cæsarean section

11 cases were treated successfully by version and delivered as vertices 9 cases were treated unsuccessfully by version Some of these were delivered vaginally and some by cæsarean section Maternal mortality nil, fœtal mortality 10%

63 cases were delivered vaginally Maternal mortality nil, fœtal mortality 28 9%

26 cases were delivered by cæsarean section Maternal mortality nil, fœtal mortality 3 8%

The details of the various cases and the technique employed in each are so meagre that the reader will be unable to draw any conclusion as to the possible or probable cause of the fœtal mortality Little information was given as to how the aftercoming head was delivered

Obviously, the authors have been impressed by the low fœtal mortality associated with the cæsarean operation "It would be idle," the authors state, "to attempt to draw conclusions from a mere 100 cases" I would go further and state that it would be distinctly dangerous to draw any conclusions from this series of cases as presented Simply because the cæsarean operation has given good results in this small number of cases it cannot be accepted that the operation is the treatment of choice in breech presentation The authors state their opinion that "if breech presentation is diagnosed during the antenatal period version should be attempted , if version fails then cæsarean section is the treatment of choice" Surely this cannot be accepted External version is an operation which requires considerable experience and skill to carry out correctly It is a serious procedure and is attended by definite risks to the baby There is an increasing amount of data to prove that the fœtal mortality following external version is in the region of 5–6% Failure to turn a breech presentation into a vertex cannot be accepted as an indication for cæsarean section So much depends upon the operator and the local conditions I will grant that cæsarean section has its place like all other forms of treatment in breech cases The operation should, however, be reserved for such cases as placenta prævia, extended limbs in an elderly primi gravida or in one with slightly contracted pelvis Emergency cases, when seen late in labour with the breech presenting, present a difficult problem The easiest way out of the difficulty will, in many cases, be cæsarean section The risk of section in these cases is sepsis following manipulation or previous efforts to deliver from below

Figures prepared for me by Dr Mary Mayeur, obstetric assistant at the Liverpool Maternity Hospital, show that there are other methods of dealing with breech presentation than external version and cæsarean section

VAGINAL DELIVERY OF UNCOMPLICATED BREECH PRESENTATION

—	Primi gravidæ	Fœtal mortality (per cent)	Multi gravidæ	Fœtal mortality (per cent)
1933	32	3 1	23	4 3
1934	34	5 8	26	15 0
1935	32	9 3	21	9 5
1936	35	5 7	18	11 0
1937	27	7 4	25	nil
1938	39	5 1	21	nil
1939	45	8 8	25	4 3
1940	42	4 7	17	nil
Total	286	—	176	—

Average fœtal mortality Primigravidæ—6 23%
" " " Multigravidæ—5 5%

During the above years cæsarean section was only performed in 40 cases for breech presentation The maternal mortality was nil and the fœtal mortality 2 5%

Liverpool JOHN WILLIAM BURNS

A PITUITARY SYNDROME WITH CARDIAC ABNORMALITY

SIR,—The association between pituitary deficiency of different varieties and mental disorders of equal diversity is a commonplace observation Far less common, and only rarely appreciated, is the relationship between pituitary dyscrazia and cardiac abnormality In French literature there are one or two references to pituitary disease coexisting with vaguely defined conditions such as cardiac hypoplasia What has not been noted previously is a syndrome characterised by both cardiac abnormality and mental abnormality in patients with anterior pituitary deficiency

The cardiac abnormality has one main characteristic It is found early in these cases and is probably congenital Indeed the most characteristic heart lesions include the less dangerous varieties of congenital heart disease These patients have often been watched for heart conditions in childhood and early youth before symptoms traceable to glandular dysfunction were prominent in the picture The mental abnormalities noted are not usually psychotic The adolescent patient with these symptoms falls into the psychoneurotic category There is no characteristic collection of psychological symptoms associated with this syndrome but there is certainly a class of patients in their teens in which vaguely epileptoid phenomena are noticeable It seems possible that some of these "absences" and vague collapses may be attributable to the cardiac condition The pituitary condition present always involved diminished activity of the anterior lobe Lorraine and Brissaud phenomena are more common, but Frohlich symptoms are possible I have not met this syndrome in women

One characteristic of these cases is the complexion The skin is unusually delicate The colouring is lightly cyanotic This hue is chiefly over the malar bones and sometimes lower down in the centre of the cheek The rest of the skin is faintly yellow This yellow colour becomes intensified in long-standing cases Cyanosis and yellow tinting of the skin are found in many conditions, but this peculiar cyanosis combined with the delicate texture of the skin is quite characteristic

Medical News

niversity of Oxford

On Wednesday, June 4, the general medical electorate, hich consists of all Oxford graduates in medicine who are embers of convocation will elect two members to the board the faculty of medicine The members elected will come to office on the first day of Michaelmas term, 1941 The nior will hold office for two years and the junior for one year ominations will be received by the secretary of faculties at e university registry, up to 10 A.M on Wednesday, May 14 ach nomination must be signed by six members of the ectorate

niversity of Dublin

On March 19 at the school of physic Trinity College, the llowing degrees were conferred —

M.A O—O D T D Browne
M.D—R. T Jackson
M.B B Ch B.A O—A F Crowley, A H H Guilbride, J R ealy, H. B C Houston L C Jacobson, Bernard Kernoff, C D acCarthy, M. A Majekodunmi Kathleen M Patterson, Alicia Pike, Simon Smullen and W J Thompson

ational University of Ireland

On March 6 the honorary degree of doctor of science was onferred on Dr Gordon Holmes, F R S Dr F R M Walshe, nd Prof E Hey Groves Apart from their scientific stinction, the three graduands have personal associations ith Ireland Dr Holmes is a native of Co Louth and as educated at Trinity College, Dublin, where he took his edical degrees in 1898 and in 1933 the college conferred on im the honorary degree of D Sc Dr Walshe, though not orn in Ireland, can claim Irish parentage, for his father was orn in Co Mayo Mr Hey Groves was for several years n external examiner in surgery of the university Dr alshe and Mr Hey Groves were unable to attend the raduation, but Dr Holmes was present, and afterwards elivered a lecture on neurosis and the war

niversity of Bristol

Mr J M Yoffey, lecturer in anatomy at the University ollege of South Wales and Monmouthshire, has been ppointed to the chair of anatomy in succession to Prof S E hitnall, who is shortly retiring

Mr Yoffey qualified M B from the University of Manchester in 924 and took his B Sc two years later He was awarded a Leech search fellowship in 1926 and obtained his M D with commendation in 1928, after which he held a B M.A research scholarship le was house surgeon at the Manchester Royal Infirmary, passing n to demonstrate in the anatomical department and taking the R C S in 1932 He then spent two years in America with a ockefeller foundation and first went to Cardiff as senior demon trator in anatomy He has made a special study of the lymphatic athway from nose and pharynx, and this year he delivered a unterian lecture on the subject, which will shortly be published in ur columns

oyal College of Obstetricians and Gynæcologists

At recent examinations for the D.R C O G the following ere successful —

Marie H Calverley, L E Cowan, Ursula M Dick, Marjorie O Dunster, D S Foster R R Gordon C N Gosse Ruth M Howitt, L L T Jones, Agnes M. D Milne James Overton Mary A Rogerson, C R. Slinning, Christine M Stacey, Evelyn E Steed and Lucy M Sutcliffe.

On April 2, at 4 30 P M , at the Royal Society of Medicine Dr H P Bayon will address the section of history of medicine on the conquest of lues venerea, and at the same time at the ection of surgery, Mr Jocelyn Swan, Dr C Worster-Drought and Mr W Rowley Bristow will open a discussion on peripheral nerve injuries

The house and library of the society will be closed from April 11 to 14, both days inclusive

The next meeting of the Shaftesbury Military Hospital Medical Society will be held on Saturday, March 29 at 3 P.M , when Dr Charles Newman and Mr Reginald Payne will open a discussion on the dyspeptic in the army On Tuesday, April 1, at 3 P M., Lord Horder will address the society on the *future* of medicine

A meeting of the Medical Society of London will be held at 11 Chandos Street, W 1, on Monday, March 31 at 4 30 P M , when Dr John M Converse and Mr Alan Hunt will open a discussion on the factors influencing the healing of wounds

On Wednesday, April 2 at 2 30 P M at the Royal Society of Arts, John Adam Street, London, W C 2, Lord Horder will read a paper entitled The Modern Troglodyte

Notes, Comments and Abstracts

CONTROL OF OBNOXIOUS INSECTS

BY ERIC HARDY, F Z S

IN normal times a hospital is seldom worried by insects outside its kitchens and boiler houses, but under war-time conditions there may be trouble from the use of buildings placed near farms brooks or other breeding places The hospital s chief insect visitors are house-flies, gnats or mosquitoes cockroaches and crickets Cleanliness is no precaution against them in fact if it means a predominance of white materials it may even attract flies Ventilation, however helps by keeping the air cool and dry Marking house-flies with coloured chalk has proved that they will travel 13 miles in a couple of days which means that a hospital's source of flies can be manure or refuse heaps, stable yards or cow-sheds up to that distance away

There are two house-flies causing the trouble The one which appears in spring and summer and forms jerky dancing parties under the lights is the lesser house-fly, which has three dark lines (hard to see in the male) down its somewhat slender body , it generally breeds in rotten damp paper, decaying vegetation behind old wallpaper and plaster and in rubbish The common house-fly does not appear until about July, and it is then the commonest *species until September when the females hibernate for* the winter in warm retreats ready to emerge in spring and lay their eggs The common house-fly breeds in fresh stable manure or in earth closets They contaminate food and clothes with their cushion-like feet and their hairy bodies and by their habit of feeding by ejecting a blob of saliva to dissolve the food before they suck it back in solution Their usual life is 34 days If their breeding-place can be located in a local stable, fowl-run or farmyard the manure can be sterilised chemically by sprinkling it with iron sulphate mixed with 40 parts of soil but not more than 15 tons per acre of such treated manure should be used by farms for agricultural purposes Alternatively, the fresh manure can be stacked daily on a wooden platform, supported by posts a foot high over a 4-in concrete basin kept full of water The flies will choose this fresh manure for breeding in, and when their mature maggots or larvæ leave the manure to seek a pupating site they will fall off the edge of the platform into the water trough and be drowned , up to 99% of the larvæ can be destroyed by this method If manure is forked over frequently, larvæ can be rapidly destroyed by raking them into the hot deep portions of the manure *heap Gnats or mosquitoes most often inflict bites indoors* because the biting female gnat hibernates , the males have no bite and mostly die off in autumn Although the straight-bodied *Anophelcs* mosquitoes have the worst reputation the hump-backed *Culex* species are more common The larval stage of mosquitoes is aquatic, and likely breeding grounds are the standing water in soft-water butts badly drained fields and camping sites blocked ditches and dykes

Indoors flies and gnats can be repelled by selecting certain colours for decoration H F Nuttall, with others, has shown that pale yellow repels gnats or mosquitoes , so that if curtains lampshades, fanlights, walls and ceilings are that colour they will prove a deterrent to the insects This colour scheme will also discourage—or at least not encourage—house-flies and even wasps which are attracted by whitewashed or white-painted ceilings and walls Pale blue is also more effective than white in discouraging flies, and government stables in Denmark removed their fly-trouble by using a bluewash instead of whitewash This method has critics because insects may put up with a repellant colour if no alternative offers A saucer of 10% formalin as the only available drink in a room will attract and kill flies and a 2% formalin or a pyrethrum oil spray is effective on their dancing parties Adhesive fly papers are most effective when scented with geranium or rose oil There are reliable commercial insecticides which are highly effective when used as sprays, but it is important to make sure that those chosen are really lethal and do not merely stupefy the insects temporarily

Wasps bluebottles biting grey stable flies ants and bees are as a rule only accidental visitors , if they become blood agar plates representing 10 cu ft air grew as many as 141 *Strep pyogenes* type 6 corresponding to his infecting organism These were undoubtedly derived from the enormous reservoir of floor dust which is being constantly implemented during the patient's infective stage The importance of allaying these dusts by such means as treatment of the floors with spindle oil (Van den Ende, Lush and Edward, *Lancet*, 1940, 2, 133), which our experiments have shown to be very effective for this purpose, cannot be too strongly emphasised

Shenley, Herts JOHN C THOMAS

IRRIGATION OF BURNS

SIR,—I am extremely interested in Mr Fraenkel's statement in your last issue that the hypochlorite irrigation method produces a "clear, glossy, transparent and elastic covering of the raw surfaces" This film cannot be an interfacial membrane of the Ascherson type and is akin to that produced by protein denaturation at an air/water surface, especially foam

What is common to the tannic acid, triple dye, albumin, hypochlorite irrigation, and oil treatments is the formation of a membrane Only the oil treatment, however, produces a true liquid/liquid interfacial membrane of polar-nonpolar character, providing for permeability of both lipoid- and water-soluble materials Such a film, too, is the one most responsive to the presence of ions, notably calcium ions In other words, this type of membrane is the nearest approach biologically to membrane in vivo It is the one most likely to serve as a vehicle for appropriate medication whilst still operating to seal areas whence serum would leak.

Orpington WILLIAM CLAYTON

Obituary

JAMES IAN McCONNELL

M B DURH , LIEUTENANT, R A M C

Lieutenant J I McConnell was the elder son of Dr James McConnell, school medical officer for Tynemouth He was educated at Uppingham School where he was a member of the O T C He graduated M B from the Durham College of Medicine in June, 1939, and in August was appointed a house-surgeon at the Royal Victoria Infirmary, Newcastle He resigned in the following November when he obtained a commission with the R A M C. At first he was attached to an ambulance unit but later he became a battalion medical officer with the Sherwood Foresters He took part in the Norwegian campaign and last May was reported "missing, believed prisoner of war" In December, however, news was received from the Norwegian Red Cross that he had been buried at Lillehammer on April 28. No other particulars were given

Gladstone Adams Whitley Bay

As a student McConnell worked hard but he found time to take an active part in college life and a friend who faced with him the pleasures and adversities of a medical student's life, writes "With his ready humour and disarming cheerfulness Ian McConnell was a well-known and popular figure He took a keen interest in the academic and social side of university life On the rugby field his unorthodox and often unique tactics proved a constant thorn in the side of the opponents A good companion and a true friend he was welcome at any gathering of the medical fraternity, whether on the Students Representative Council, in the University Union, in O T C camps or at medical dances—all institutions which he supported vigorously" When he could escape from his work and town life he was happiest fishing a border stream or watching bird life while

MARCUS MAX ISSERLIN

Professor Isserlin, who has died in Sheffield where he found refuge from Nazi persecution, is best known to neurologists as the author of a monograph on aphasia in the great "Handbuch der Neurologie" After graduating in 1902, he studied physiology and psychology before joining Kraepelin's staff in Heidelberg Later he followed him to Munich as research worker and associate professor, becoming head of Kraepelin's psychological laboratory During this period he was mainly concerned with the analysis of voluntary movements, he also introduced experimental phonetics into the study of anomalies of speech in nervous and mental disease During the last war he was in charge of one of the centres for head injuries in soldiers, after the war Isserlin's genius for organisation made it a unique place for the treatment, aftercare and vocational guidance of cerebral injuries With American help he built the Heckscher Institution for nervous disease which originally admitted war victims only, but was later enlarged to admit civilian patients after accidents and defective children It consisted of an outpatient department, a hospital for temporary treatment, a home for invalids, curative workshops, laboratory, and a statistical and follow up department for cases of cerebral injury in the Southern contingent of the German army Isserlin's interest centred more and more round the disturbances of speech, and these patients provided rich material for study which culminated in his monograph on aphasia and in a series of articles on the patho-physiology of speech Combining as he did a wide experience in cerebral symptomatology with a thorough knowledge of modern psychology he was able to replace the association psychology, employed by the diagram makers of aphasia, with modern views still retaining well-established principles of localisation in the brain It had been his hope that some of his experience might be of use here and now in the care and treatment of cerebral injury

EFFORT SYNDROME

DIAGNOSTIC AND THERAPEUTIC VALUE OF EXERCISES

BY SIR ADOLPHE ABRAHAMS O B E, M D Camb, F R C P
PHYSICIAN TO THE WESTMINSTER HOSPITAL

THE term effort syndrome is one which we employ, in default of a better, appreciating that none will be universally acceptable It meets the generally established definition of the condition as one of ill health in which the signs and symptoms produced in normal subjects by excessive exercise are called forth by lesser amounts and in which no physical signs of structural disease are discovered Alternatively it may be defined as an abnormal physiological reaction to effort with the production of breathlessness, disproportionate or premature exhaustion, palpitations, precordial pain, faintness, dizziness and blurred vision

Were such definitions unexceptionable, it would be reasonable to regard the subjects as exhibiting merely a depressed capacity for exertion The cause of such an incapacity might be matter for investigation but at least it could be agreed that since physical ability is only relative the subjects under consideration are merely those who stand at the bottom of the scale To such conclusions there are cogent objections, the first being to the question-begging adjective " excessive " as applied to exercise for normal individuals I would prefer strenuous, severe violent or extreme Secondly, no degree of exercise however strenuous will produce in a healthy person the outstanding symptoms which are produced as the result of a minor degree of effort in a subject of this syndrome, and which are, moreover, to some extent present in him even without antecedent effort

Graduated exercises have been recommended as a kind of universal treatment The differences in individual athletic ability are well recognised, but it is argued that by exercise some degree of improvement is possible to everybody and that the grading which in consequence results will be of practical value On this reasoning effort syndrome would be equivalent to the " out of condition " state, and would demand a course of training more or less analogous to that of an athlete preparing for a contest Exercises have their use but their application is limited A course of physical training will usually benefit the under-developed, ill-nourished youth who has lived under bad conditions, physical and hygienic, and who partly from disinclination partly from lack of opportunity has never taken exercise In him the reduced capacity for exertion is a real example of " unfitness " and he may be trained in the orthodox sense It is often forgotten that under service conditions all sorts of advantageous circumstances are operating simultaneously good and plentiful food, regularity in living, absence of anxiety about employment and a feeling of security on this score, discipline, and an ordered life which ensures moderation in tobacco and alcohol, and the avoidance of bad habits The rapid improvement in physique and capacity for effort which occur in such a type are advanced as evidence of the universal value of " P T ," but though P T plays a part the part is not the whole

Subjects of postinfective asthenia often exhibit an incapacity for effort, and some infections are particularly potent in this respect, especially trench fever and influenza It is sometimes maintained that myocardial weakness is the cause of such incapacity, but it is far more likely that the infection has affected the vasomotor system Vasomotor stability will return in time without treatment, but its return will be hastened by such exercises as can be carried out without distress

The toxæmic element in such cases has encouraged the belief that all, or most, sufferers from effort syndrome are victims of chronic sepsis, the eradication of which is of primary importance Teeth and tonsils are the commonest sources of infection, followed by more remote possibilities such as the appendix, the gall-bladder and the prostate, or such nebulosities as " intestinal toxæmia " If the net cast is sufficiently fine the instruments of precision sufficiently sensitive and the investigation sufficiently exacting, it is possible to find some plausible abnormality in almost anybody Latent tuberculosis and thyrotoxicosis have their adherents, while extrinsic toxins such as tobacco are indicted as additional rather than primary influences As in the practice of medicine generally, the enthusiasts for focal sepsis occasionally score brilliant successes but encounter far more disappointments It is well to eradicate an obvious source of sepsis but it is the experience of most observers that the number of cases of effort syndrome which can be attributed to this cause is exceedingly small.

MUSCLE AND MIND

If properly organised, exercises have a psychological value Their character must be varied, they must be intrinsically interesting instead of mere monotonous repetitions of stereotyped movements and they must demand unremitting attention In this way it is possible to ensure half an hour's sustained activity in a man who would fall out in five minutes of the tedious procedure comprehended under the one-time P T The man who has entertained the conviction that he has a cardiac defect, or at least a constitution, which must not be subjected to the hazards of exertion may be reassured by discovering that exercise does not lead to calamity and not even, after a time, to symptoms which he had supposed to indicate " heart weakness " or " heart strain " As a member of a suitable class he will have the advantage of encouragement, competition and emulation, and may come in due course to take a pride in achievement and the cultivation of fitness At the same time it is best that he should be occupied in a useful and interesting manner for most of the day, so that he has no time for introspection or for undesirable habits which are often the consequence of boredom

Exercises serve a useful purpose in grading If a man can accomplish half an hour of systematic vigorous exertion and at the end exhibit no distress and no undue delay in deceleration of the cardiac rate, his circulatory integrity is established and there is no reason why the physical requirements of an ordinary military life should not be met But no system of exercises can test the reaction to unalluring or distasteful circumstances or guarantee that symptoms and even physical signs will not be forthcoming when escape is sought from an intolerable situation This is a psychological problem and it must be left to the psychiatrist, not to the clinical physician, to assess the individual's probable reaction to circumstances and responsibilities

It is comparatively easy to recognise the subject of post-infective debility and the under-developed type that can be improved in the manner described But the crucial problem is in respect of the fundamentally unsound is the essential fault ascertainable and eradicable or must a fatalistic view of complete failure be accepted ? Exercise is a complicated process into which enter a variety of factors, including the myocardium, the blood, the respiration, the muscles in their biochemical aspect, the nervous system and the mental outlook It is a simple but defeatist conclusion to regard the nervous as the essential factor in effort syndrome, when jerky maladjustment displaces orderly coordination In such cases, exercises, far from producing any improvement, are likely to aggravate the symptoms This applies at any rate to exercises of the usual P T type, although it has been suggested that better results might be expected by a system more minutely graduated in which encouragement would presumably play a great part

The exercise-tolerance test is often condemned as inadequate or useless, although it is not easy to ascertain what exactly the critics have in mind or what they suppose it is intended to test All that can be determined is the capacity for exertion as indicated by circulatory efficiency But nothing can test the willingness of the man, and here those responsible for the disposal of subjects of effort syndrome have an obvious difficulty A man may exercise vigorously without distress and demonstrate the integrity of his circulation, and may yet complain of various subjective sensations regular ones there must be a nearby breeding source Wasp-nests may be in the ground, among tree roots, in rat or rabbit holes, in banks, in hollow trees, or even suspended in outhouses The nest has to be located and then when all the wasps have returned at dusk, creosote or petrol is poured down and the entrance well plugged up Ants' nests under stones, steps or flag paths, or in banks and so on are treated likewise, though the common dusky brown ant is largely a nocturnal wanderer

Cockroaches and crickets can be dealt with in much the same way The noise of the cricket is its chief annoyance—a single ungetatable cricket can be as upsetting in the ward at night as an air-raid—but the cockroach may do damage by contaminating food The most effective way of controlling both is with a simple trap, made from a glass jam jar baited with cooked vegetable, banana, orange peel or meat flavoured with aniseed or beer, and fitted with an inverted cone cap of stiff smooth art paper, with sufficient space for the insect to slip through A sloping gangway or steps up to the top of the cone must also be provided The smell of the bait attracts the hunting cockroach or cricket at night, and it will slip down the cone into the jar A number of such traps can be placed in likely haunts in the evening and the captives tipped out into boiling water next morning Where kitchens or boiler houses are heavily infested with these insects, it may be better to fumigate the rooms with sulphur dioxide, by burning 2 lb of sulphur for each 1000 cu ft room and keeping the room sealed for 36 hours Poison baits for cockroaches and crickets can be made from 3 parts of sodium fluoride to 1 part pyrethrum powder, or borax and pyrethrum flavoured with castor sugar or chocolate Sprays to fetch crickets and cockroaches out of the cracks and crevices of their retreats can be made from ½ lb pyrethrum powder in 1 gallon of paraffin This is decanted and 2 oz of methyl salicylate, or acetic acid added

The house-mouse may be attracted, like cockroaches, by surplus food material, and in autumn and winter field mice and house mice are driven indoors for warmth They are probably never numerous enough to require sulphur or cyanide fumigation, and the latter in any case is best confined to outdoor rat-holes Individual traps or poison baits should be varied and numerous (ten per head of the estimated mouse or rat population) and should be placed in the most frequented haunts of the rodents, which are discovered by examining dusty pipes and corners for footmarks Bait should compete with the available food-supply Bread and cheese merely imitate the scraps which can be found in the kitchens and larders, and a more attractive bait would be minced bloater or kipper, oatmeal or rolled oats, it should not be flavoured with aniseed or it will attract cockroaches A useful bait, harmless to domestic animals, can be made from 1 part by weight of liquid extract of red squill, 2½ parts of fine oatmeal or rolled oats and 1½ parts of dripping or castor sugar, the fat is melted to mix the rest into a paste and the final product is wrapped in twists of tissue paper A useful deodorant for mice, cockroaches and the like is zinc chloride or nitrate of lead This may be either squirted into mouse-holes, or a sheet may be dipped in the solution and suspended

Buildings can be made mouse and rat proof by stopping all holes with cement reinforced with broken crockery or glass, or plugging them with a poisonous paste of barium carbonate and dripping so that the rodents are poisoned when they gnaw their way out Foundations should be set in concrete, all basement windows, drains, drain-pipes and ventilators should be covered with mesh wire, and the bottoms of outside doors should be covered with a sheet of brass or zinc to prevent rodents gnawing their way in All food bins should be of metal

WE have now received from America the January number of the new *Journal of Clinical Endocrinology* This medical paper is being published monthly for the Association for the Study of Internal Secretions which controls *Endocrinology* The two journals will aim at being complementary, experimental work being largely segregated in the old journal and its practical applications in the new The annual subscription is $6 50 and the publisher Charles T Thomas, 220 East Monroe Street, Springfield, Illinois

CHEMOTHERAPY OF WOUNDS —In some of the systemic infections the technique of chemotherapy seems to be established, though no doubt improvements both in the choice of drug and its dosage will continue to be made In surgery, however, the possibilities of the sulphonamide drugs are only beginning to be revealed, and it is no easy task to lay down rules for their use Messrs May and Baker of Dagenham have produced a well-documented booklet in which the present position of chemotherapy in the prevention and treatment of infection in wounds is clearly explained and they will do the practitioner a useful service by keeping the booklet up to date This they clearly intend to do, for a revised edition has appeared within a few weeks of the first It is obtainable free of charge on request

---

Air Commodore F C Cowtan has been appointed an honorary surgeon to the King in succession to Air Marshal Sir Victor Richardson, who has retired

The volunteer officers' decoration has been awarded to Surgeon Commander F. L Cassidi, M B Camb

An election of junior Beit fellows for medical research will be made in July The fellowships are normally of the annual value of £400 for three years, and candidates must hold a registrable medical qualification Elections are rarely made above the age of 35 The trustees wish to further research in mental disease, and preference will be given to a candidate proposing research in that subject Applications should be sent by May 14 to Prof T R Elliott, F R S, at University College Hospital Medical School, London, W C 1

Roche Products (Welwyn Garden City, Herts) have opened a branch office at 166, Buchanan Street, Glasgow, C 1

Appointments

AIREY, F S, M B Edin, M R C P E dermatological referee for Circuits 18 and 19

DICK, NANCY K, M B Lond deputy medical superintendent at South Middlesex Fever Hospital, Isleworth

HOWTS, ELLEN, M R C S temp asst to school M O and to M O H for Brighton

RIBEIRO, C O, M R C S examining factory surgeon for Knowbury, Salop

SHALDERS, GERTRUDE, L D S, D M Vienna asst dental surgeon for Ilford

STANDRING, THOMAS, M D Lond deputy M O H for Woolwich

WILSON, R S, L R C P E, D P M, L D S deputy medical superintendent at the North Wales Counties Mental Hospital, Denbigh

Birmingham City Council —The following have been appointed temp M O s for maternity and child welfare —

BEBBINGTON, EVELYN F, M B Lpool D P H,
FLEMING, MAY E M, M B Glasg, D P H, and

Births, Marriages and Deaths

BIRTHS

GRAHAM —On March 11, at Lahore, the wife of Major G K Graham, I M S —a daughter

JEREMY —On March 16, at Cambridge, the wife of Flight Lieutenant W H R Jeremy, M B, R A F V R —a daughter

MATHESON —On March 16, in Edinburgh, the wife of Dr Alister R Matheson—a son

MAYON WHITE —On March 18, at Sutton, Surrey, the wife of Dr R M Mayon White—a daughter

MEIKLE —On March 19, at Malvern, the wife of Dr Gilbert J Meikle—a son

SANTOW —At Hamilton, N S W, the wife of Dr G S Santow—a son

SARKIES —On Feb 1, at Mandalay, the wife of Capt J W R Sarkies I M S —a daughter

VAUGHAN —On March 8, at Barnard Castle, the wife of Surgeon Lieutenant Cyril Vaughan—a daughter

MARRIAGE

HENRY—BENNETT JONES —On March 22 at Liverpool Leon Henry, F R C S, to Patricia Mary Bennett Jones, M B

DEATHS

ILLIUS —On Feb 13 at Funchal, Madeira, Henry Warwick Illius C I E, F R C S E lieut colonel, I M S retd

JACKSON —On March 19, at Harrogate, Basil Frederic Forrester Jackson, M R C S, of Upper Richmond Road, Putney

MITCHELL —On March 15 in Birmingham Thomas Ellis Mitchell, L M S S A, captain R A M C, aged 34

SMYLY —On March 19, [illegible] Smyly, Kt, M D T operative measure necessary to relieve the obstruction. In Warthen's series simple release was practicable in only 37% of cases compared to our 66.5% and his total fatality was correspondingly higher, 34% to our 22.4%.

THE DANGERS OF RESECTION

In 62 out of our 670 cases part of the gut was not considered viable and a resection was carried out. 48 of these died, a fatality-rate of 77.4%. Of our 300 cases of strangulated external hernia 30 required a resection of gut and 24 of these died, a fatality-rate of 80%. Of the 270 cases in which simple release was practised only 18 died, a fatality-rate of 6.7%. Why should there be this appalling difference in the prognosis when the gut changes from viable to non-viable? It has been claimed that patients in whom a resection is necessary are already desperately ill, that they are suffering from the effects of extreme dehydration and absorption of toxins and are therefore unable to stand the effects of an operation, or that although able to stand a short operation they cannot stand the necessary gut resection. If this were so one would expect that in the vast majority of fatal cases the patient would die at any rate within a day or so of operation. In actual fact this explanation of the high fatality is entirely false. In a few of our 62 cases of resection the patient was in extremis on admission, and, in spite of efforts at resuscitation and an operation carried out as speedily as possible at what was considered to be the optimum moment, died soon afterwards. In a considerable number of cases, however, the patient was not in extremis and there were no systemic signs whatever, the discovery of non-viable gut being apparently quite unexpected. This was particularly common where the strangulated gut was outside the general peritoneal cavity—in an external hernial sac. In the majority of cases there was a moderate degree of dehydration or toxæmia but certainly not enough to render the patient unfit to stand a resection of gut, which need not cause much operative shock if certain technical details are observed. Nor does the patient necessarily die soon after operation. A certain number, of course, do die rapidly, overwhelmed by toxæmia or general peritonitis present before operation as a result of perforation of gangrenous gut. But the majority survive the immediate hazards of operation and the next few days. These may die at any time up to six weeks after operation, the commonest danger periods being about the fifth and about the tenth day. The symptoms are typical of an increasing mechanical obstruction—colicky pains, exaggerated peristalsis, vomiting and increasing distension. At autopsy the cause of death is found to be a plastic peritonitis of a variable but fatal degree, with much adhesion of gut to gut, and gut to abdominal wall, and an œdematous intestine full of foul material, with multiple sites of obstruction.

THE CAUSE OF LOCAL PERITONITIS

Were it possible to eliminate this local peritonitis the fatality of gut resections would drop considerably. It seems certain that the organisms producing it must have come from inside the gut. They may reach the peritoneal cavity before, during, or after operation. Before operation, organisms might conceivably pass through the damaged gut wall before actual gangrene had occurred, and clearly the peritoneum will be flooded with organisms if a gangrenous coil of gut lying in the peritoneal cavity perforates. At operation, however good the aseptic technique, organisms are bound to escape when the gut is opened. After operation, since only undamaged gut is left, organisms are only likely to escape if the anastomosis leaks.

It seems unlikely that in most cases fatal contamination of the peritoneum takes place before operation. Thus, in our series actual perforation was rarely found; it was only in these few cases that obvious signs of peritonitis were present and then only if the perforated gut was lying in the general peritoneal cavity. Moreover, the fatality-rate after resection of a coil of gut lying in an external hernial sac and sealed off from the general peritoneal cavity was 80%, while the mortality after resection of a coil which had been lying in the general peritoneal cavity was actually slightly less, 75%. If the passage of organisms through the gut wall was of significance one would imagine that the fatality would be much higher in cases where the gut was inside the peritoneal cavity.

Contamination of the peritoneum by leakage of the anastomosis after operation is also not of importance in the majority of cases, for at a second operation or autopsy there was asserted to be evidence of leakage in only one case in our series. The areas of plastic peritonitis, although in the region of the anastomosis in most cases, are not necessarily so, and the area around the anastomosis is sometimes free from adhesion or peritonitis, which is centred in another part of the abdomen.

Some organisms probably do pass through the gut wall before operation but not to a great extent unless gangrene and perforation have occurred; the main contamination of the peritoneum probably takes place at operation and is due to the gut being opened. In support of this view, 3 of the cases of gangrene in our series were treated by exteriorisation with the intention of performing a subsequent operation for the reconstruction of the normal intestinal tract. Of these, 2 survived, but both of them died after the second operation for closure of the fistula, the surgeon being forced to open the peritoneal cavity and the gut. If we divide our 670 cases into two groups according to whether the gut was opened or not we find that of 224 cases in which the gut was opened 137 died, a fatality of 61.2%; 68 of these were small gut, 54 dying, a fatality-rate of 79.4%; 156 were large gut, with 83 deaths, a fatality-rate of 53.2%. But of the 446 cases where only simple release was necessary 23 died, a fatality-rate of 5.2%. The prognosis in the cases requiring opening of the gut was necessarily much worse, but nevertheless the difference is so great as to suggest that opening the gut provides a new lethal factor sufficient to weigh the scales against the patient.

THE PROGNOSIS

This, then, is the prognosis of acute intestinal obstruction. If simple release can be practised the outlook is good, the fatality in our series being only 5.2%. If the gut has to be opened, either to perform an anastomosis, to drain the gut or to perform a resection, the prognosis is much worse, in our series the fatality being 53.2% in large-gut and 79.4% in small-gut obstruction. In cases requiring resection of gut the rate was 77.4%. A reduction in the deaths from acute intestinal obstruction can be attained in two ways: by earlier diagnosis and by more successful treatment and prevention of the lethal complications which result from delay in diagnosis. With a view to preventing such complications we have carried out a series of animal experiments.

Experiments with Intraperitoneal Sulphanilamide

We have employed oral chemotherapy in the treatment of postoperative peritonitis, but to our disappointment it was unsuccessful and in one or two cases even seemed to have a deleterious effect. We therefore devised experiments on rabbits with the object of ascertaining (1) whether deliberate contamination of the peritoneal cavity with the contents of the gut does in fact cause a plastic peritonitis of the kind often found in man after a resection of gut; (2) if so, whether there is one causative organism which can be recovered later from the infected peritoneum and grown in pure culture; (3) whether such a peritonitis can be prevented or modified by the local application of sulphanilamide into the peritoneal cavity; and (4) if so, whether oral sulphanilamide is as effective as intraperitoneal sulphanilamide.

FIRST EXPERIMENT

As a preliminary investigation, a suspension in saline of 300 mg of sulphanilamide per kg body-weight was injected into the peritoneal cavity of each of two rabbits, a dose equivalent to about 15 g in man. Blood was taken at intervals and its sulphanilamide content estimated. It was found that absorption was completed in 30 hours, and the drug produced no ill effects or local reaction in the peritoneum.

SECOND EXPERIMENT

The next experiment was carried out to ascertain the effect of intraperitoneal sulphanilamide on the reaction of the peritoneum of rabbits to the organisms inside their own gut. The abdomen of each of 12 rabbits was opened and intestinal contents withdrawn through a small (exhaustion, giddiness or precordial pain) either soon after or sometimes two or three hours after completing the effort

In the last war I was familiar with one of the greatest athletes in the world, capable on the running track of extreme exertion, who evaded military service by presenting symptoms and even physical signs, such as fainting, whenever military duties were demanded What attitude should be taken in such circumstances ? Psychologists maintain that to ignore complaints in the absence of physical accompaniments, and perhaps to enforce strict military discipline, is only to court the production of more and worse symptoms , but the modern medical officer has sufficient sense of duty, confidence in his clinical knowledge, and courage to take trivial risk, instead of referring all cases for special investigation More rarely the converse problem arises, that of a man who at the end of his exercise has a protracted tachycardia despite his assertion of well-being Subjectively considered, he is fit to be returned to his unit where he may well carry on , but he may report sick under stress, especially emotional stress, when objective signs will be discovered which cannot be ignored

PHYSICAL BASIS OF SYMPTOMS

Since there is often tachycardia, the influence of the thyroid is naturally invoked and in a few instances there is evidence in favour of this explanation On investigation, however, fundamental objections appear At rest, the circulation of the hyperthyroidic patient resembles that of a normal person during exercise there are tachycardia, increased cardiac output and accelerated blood flow These factors are absent in the patient with effort syndrome, and he also fails to exhibit that constant feature of the hyperthyroidic, persistence of tachycardia during sleep

Normally exercise results in a slight acidosis, a relative reduction of blood alkalinity which is the stimulus for increased respiratory effort It has been thought that the patient with effort syndrome may be hypersensitive to an acid intoxication of a degree which in a normal person will produce no respiratory distress or over-activity This might be explained by a constitutional deficiency in the buffer substances of the blood—sodium bicarbonate, sodium phosphate and proteins—which normally combine with carbon dioxide and other metabolic acids Even at rest the subject of effort syndrome may display shallow ineffective respiration He gives the impression, not of dyspnœa but of lazy breathing, of never having acquired the habit of accumulating enough CO_2 to afford the respiratory centre the necessary stimulus As would be expected, response to the breath-holding test is exceedingly poor The effects of hyperventilation in healthy subjects have naturally encouraged the expectation that some of the symptoms of effort syndrome might be explained in this way But Guttman and Jones (1940) have satisfied themselves that when patients with effort syndrome practise hyperventilation, the cardinal symptoms are produced in very few cases , no patient in their series complained of suffocation, palpitation and left-chest pain

The respiratory phenomenon of effort syndrome can only be described in general terms as an expression of disordered metabolism, possibly the result of suprarenal dysfunction The abnormal sweating has provoked speculation both on the chemical side and the relation to heat loss It is another indication of the sympathetic imbalance which characterises the syndrome and which is associated, in some instances, with vagotonia, in others with vagal insufficiency and with a general want of muscular tone especially of the abdomen The interaction of the sympathetic nervous system with the endocrines is of course familiar

To attempt to establish a uniform ætiology in cases of effort syndrome is fallacious In typical examples we recognise many of the physical accompaniments of anxiety, and the chief hope of amelioration lies with the psychotherapist whose task must be to identify the chronic emotional state—conflict, fear and the like—which may be responsible The difficulty of investigation, great enough in ordinary circumstances, is substantially enhanced by the circumstances of military service where the perpetuation of the disability is to the patient's advantage

SUMMARY

Effort syndrome is a term vaguely employed to describe a symptomatology which may arise from various causes, some of which are constitutional and ineradicable, some pathological and amenable to treatment

Exercises, combined with good food and a regular life, will benefit cases of postinfective debility or under development, but even in these their psychological value must not be overlooked

In cases of effort syndrome which seem to arise from constitutional inferiority and to have no responsible physical defect the results of physical therapy have been disappointing Their ætiology and treatment are the concern of the psychiatrist

THE PROGNOSIS OF ACUTE INTESTINAL OBSTRUCTION

EXPERIMENTS WITH INTRAPERITONEAL SULPHANILAMIDE

BY

RUPERT VAUGHAN HUDSON,
F R C S
SURGEON TO MIDDLESEX HOSPITAL

RODNEY SMITH,
M B LOND , F R C S
ACTING SURGICAL REGISTRAR AT THE HOSPITAL

AND

F R SELBIE,
M D ABERD
RESEARCH ASSISTANT IN THE BLAND SUTTON INSTITUTE OF PATHOLOGY AT THE HOSPITAL

DURING the last twenty years important advances have been made in the treatment of many acute abdominal conditions, and fatality-rates have correspondingly fallen In acute intestinal obstruction, however, while progress has certainly been made, the fatality-rate in most published figures is still between 20% and 30% In an attempt to ascertain the factors responsible for this high figure a series of 670 consecutive cases has been analysed at this hospital, and the results have been compared with those of Burgess (1923) and Warthen (1936) because their classification is sufficiently similar to the one we have adopted

Burgess published a series of 1278 cases, with a fatality rate of 28 8% In our series the rate is 22 4% In both these series the two commonest single causes of obstruction were strangulated external hernia and carcinoma of the colon The fatality-rate of acute on chronic obstruction from carcinoma of the colon was 34 1% in Burgess's series , in our series it is 31 6% In Burgess's figures the fatality-rate of strangulated external hernia was 23% , in our series it is 14%, and the fatality-rate of all small-gut obstructions is only slightly higher, 16 7% There is, then, a great improvement in the prognosis of strangulated external hernia and of obstruction of the small gut, but very little in the prognosis of acute on chronic large-gut obstruction Of the factors responsible for the improved outlook in obstruction of the small gut probably the main one is earlier diagnosis and earlier operation Holt (1928), urging the importance of the time factor in acute obstruction, says that in his cases there was a fatality-rate of about 60% in the late cases exhibiting systemic signs Warthen found that among white patients the fatality-rate was 19 5%, while it was 42 3% in blacks, and that, on an average, the time elapsing between onset of symptoms and admission to hospital in blacks was about double that in whites

It is generally agreed that the high fatality in late cases is due to complications Is there a single complication which is sufficient to alter the entire outlook ? The complications which may arise are —

1 Dehydration and chloride loss
2 Absorption of toxins
3 Vascular damage to the gut wall, the final result of which is gangrene, perforation, and if the gut is lying in the general peritoneal cavity peritonitis

Of these, vascular damage to the gut is of vital importance because, even in the absence of gangrene, it often means that simple release of the obstructed gut is not sufficient and that further operative measures have to be taken Dehydration and toxæmia are not difficult to treat per se, provided that simple release is the sole

TABLE II—THIRD EXPERIMENT Operation resection of part of terminal ileum, ileo cæcostomy

Treatment	Rabbit no	Killed or died	Post mortem findings			
			Wound	Anastomosis	Peritonitis	
					Local	General
None	13	D in 36 hrs				+ + + (Culture *B coli*)
	14	K after 3 wks	Adherent to gut	Patent Inflamed	Abscess 1 × ½ in at blind end	+ + (Culture *B coli*)
	15	K after 3 wks	Abscess 2 × 2 in discharging through wound	Patent Much inflammation	Blind end covered with lymph, adherent to small gut	+ + A few small abscesses Gut adherent (Culture *B coli*)
	16	D in 36 hrs				+ + + (Culture *B coli*)
	17	K after 3 wks	Abscess 2 × 1 in in and behind wound	Patent but surrounded by peritonitis	Abscess ½ × ½ in round blind end with much adhesion of gut	+ + involving small gut, mesentery and omentum (Culture *B coli*)
	18	K after 3 wks	Gut adherent to abdominal wall behind wound	Patent but surrounded by peritonitis	Abscess ½ × ½ in round blind end with much adhesion round it	+ + involving small gut mesentery and omentum (Culture *B coli* and *Staph albus*)
Intraperitoneal sulphanilamide 300 mg /kg	19	K after 3 wks	Normal	Patent pin s head abscess on suture line	None at blind end	None
	20	K after 3 wks	Normal	Patent not inflamed	Inflammation round blind end (Culture *B coli*)	None
	21	K after 3 wks	Abscess 2 × 1 in in and behind wound (Culture *Staph aureus*)	Patent	Blind and adherent to wound	No general spread
	22	D in 36 hrs				+ + + (Culture *B coli*)
	23	D in 36 hrs.				+ + + (Culture *B coli*)
	24	K after 3 wks	Normal	Patent One flake of lymph on suture line	Blind end not inflamed	None (Culture sterile)

prevented or modified in the same way by intraperitoneal sulphanilamide In these experiments the animal used was again the rabbit End-to-end or side-to-side anastomosis after a resection of small gut was found to be technically difficult, owing to the extremely small size of the gut The first few rabbits in which this was the technique adopted all died rapidly of obstruction or leakage at the anastomosis Ultimately, it was found much simpler to resect several inches of terminal ileum, close the lower end, and implant the upper end into the cæcum This was our standard procedure in 12 rabbits In 6 of them the operation concluded with the intraperitoneal injection of a suspension in saline of 300 mg per kg of sulphanilamide The other 6 received no sulphanilamide After three weeks all the surviving rabbits were killed and a note was made of the signs of inflammation in the wound, at the anastomosis, at the blind end and in the general peritoneal cavity Cultures were taken from each case

Of the 12 rabbits 4 died within 36 hours of operation of general peritonitis, the *B coli* alone being grown from the peritoneum in every case, 2 had received sulphanilamide, 2 had not The remaining untreated rabbits (4) developed inflammation in the wound, at the anastomosis and at the blind end, as well as widespread peritonitis It was remarkable to note the degree of peritonitis compatible with survival in the rabbit, the organism in every case was the *B coli* Of the 4 surviving rabbits treated with sulphanilamide 2 had insignificant local lesions and nothing else in 1 there was considerable inflammation round the blind end of the ileum, from which region *B coli* was grown, and one had a large abscess posterior to the wound, giving a growth of *Staph aureus* In none of these 4 was there any general peritoneal spread These results are shown in table II

We next tried to assess the value of intraperitoneal sulphanilamide when a coil of strangulated and gangrenous gut is resected Strangulation with gangrene was easily produced in rabbits by bringing a coil of gut through the linea alba, closing the incision round the gut and suturing the skin over it Unfortunately, the subsequent resection of the gut proved to be far more lethal than we had hoped Only one of many operated on survived more than 24 hours It is noteworthy, however that this rabbit, which received no sulphanilamide, lived for 9 days and died of *B coli* peritonitis with many adhesions and several sites of obstruction. The high fatality in rabbits suggests that further experiments on these lines might usefully be performed on animals better able to stand the immediate hazards of operation Nevertheless granted that the bacterial content in strangulated gut is higher and the organisms are more virulent than in normal gut, they are the same organisms and cause the same type of peritonitis It follows that any prophylactic measure which will prevent or modify *B coli* peritonitis after resection in the absence of gangrene will have a similar value in cases of resection of gangrenous gut

CASE-RECORDS

During the course of these experiments we had the opportunity of using intraperitoneal sulphanilamide in 2 cases in which a resection of small gut for acute obstruction was necessary

CASE 1 —A man of 67 was admitted with signs, symptoms and radiological evidence of acute obstruction of the terminal ileum Operation by one of us (R S) revealed a new growth which had almost obliterated the lumen of the gut Resection of 11 in of ileum was followed by the performance of an end to side anastomosis with an ileostomy just proximal, and 10 g of sulphanilamide suspended in saline was left in the peritoneal cavity Postoperatively continuous gastric suction ensured that depression of peristalsis should not lead to distension of the gut Convalescence was complicated by the development of *B coli* abscess in the wound, but from the first day the physical signs and symptoms, the study of the fluid balance chart and routine straight radiograms of the abdomen demonstrated that the anastomosis was patent and that there was no hold up anywhere along the small gut Five weeks after operation the patient died suddenly from a massive hæmatemesis from an œsophageal varix caused by puncture in the cæcum Although we were primarily interested in the organisms in the small gut, contents were withdrawn from the cæcum because the small gut was nearly always found at operation to be empty, and it was not considered probable that the organisms living just distal to the ileo-cæcal valve would differ from those just proximal Moreover, the puncture in the cæcum could be easily closed, while the lumen of the small gut was so small that it was feared that any attempt to make certain that the puncture did not leak after operation would result in undue narrowing of the gut The puncture was closed with a fine catgut purse-string suture and the intestinal contents withdrawn were then injected into the right half of the peritoneal cavity, from the right hypochondrium to the right iliac fossa In 3 of the rabbits the abdomen was then closed In 6 others, before closing the abdomen, a suspension in saline of 300 mg of sulphanilamide per kg body-weight was injected into the peritoneal cavity In 3 others the abdomen was closed and the rabbit was then given the same dosage of sulphanilamide through a stomach-tube After a week each rabbit was killed and the abdomen opened and examined The findings are summarised in the table

CONTROLS, NO SULPHANILAMIDE

Rabbit No 1—Gut adherent to anterior abdominal wall at site of the puncture, over area ½ in × ½ in Abscess ½ in × 1 in in right flank, at this point large gut was adherent to small with kinking of the latter and gut was adherent to anterior abdominal wall over area 2 in × 1 in

No 2—Gut not adherent to abdominal wall At site of puncture, not in contact with abdominal wall, there was an abscess 1 in × 1½ in from which had spread a local peritonitis involving several coils of gut over area of 3½ in × 2½ in Multiple small abscesses on posterior surface of anterior abdominal wall, from right iliac fossa to right hypochondrium Under pylorus large gut adherent to small with small abscess Scattered flakes of lymph throughout left side of abdomen Injection of mesentery of whole of small gut

No 3—Gut adherent to abdominal wall over site of puncture with localised abscess 2 in × 1 in Small localised abscesses in liver Abscesses throughout abdomen, localised by adherent coils of gut and mesentery Injection of whole peritoneum—general peritonitis

INTRAPERITONEAL SULPHANILAMIDE

No 4—Localised peritonitis, ½ in × ½ in around site of puncture, where gut was adherent to anterior abdominal wall No spread outside immediate locality of puncture

No 5—No adherence of gut to anterior abdominal wall, but abscess ¼ in × ¼ in on surface of gut at site of puncture and abscess ¼ in × ½ in on posterior surface of anterior abdominal wall under incision Some injection of pelvic peritoneum but no adhesion A few tiny flakes of lymph on posterior surface of anterior abdominal wall on right side, and two small flakes on anterior surface of left lobe of liver

No 6—Gut adherent to abdominal wall at site of puncture *over area 1 in × ¾ in No abscesses, no lymph, no* adhesion of gut to gut and no peritonitis

No 7—Gut adherent to abdominal wall at site of puncture where an abscess ¾ in × ½ in was surrounded by zone of local peritonitis 1 in × 1¼ in Mesentery of a coil of gut in this zone rather injected Elsewhere no peritonitis, no adhesions and no abscesses

No 8—Gut not adherent to abdominal wall, but under incision there was an abscess ¼ in × ¼ in which had discharged through wound At site of puncture very slight reaction and piece of catgut still undissolved, mesentery of one coil of small gut in contact with this rather injected, but no adhesion there or elsewhere and no distant abscesses or peritonitis

No 9—No adhesion of gut to abdominal wall Inflammatory reaction on posterior surface of anterior abdominal wall under incision and at site of puncture, where localised peritonitis ¼ in × ¼ in Nothing else abnormal found

ORAL SULPHANILAMIDE

No 10—Gut adherent to abdominal wall over site of puncture No abscess there, but much adherence of gut to gut with nodules of lymph Many distant small abscesses with obstructive adhesions and peritonitis Whole of small gut and its mesentery injected

No 11—Gut adherent to abdominal wall over area 1 in × ¾ in and small gut adherent to large and obstructed in this area Injection of mesentery of this coil of small gut A few scattered small abscesses elsewhere, and in region of pylorus gut firmly adherent to gut with much injection of mesentery of small gut

No 12—Obvious general peritonitis and intestinal obstruction Multiple small abscesses ¼ in × ¼ in connected by strings of mucopus across general peritoneal cavity Gross dilatation of one coil of gut which was deep purple

TABLE I SECOND EXPERIMENT

FINDINGS AT AUTOPSY A WEEK AFTER PUNCTURE AND CLOSURE OF CÆCUM AND SOILING OF RIGHT SIDE OF ABDOMINAL CAVITY WITH CÆCAL CONTENTS

Treatment	Rabbit no	Lesions at site of puncture into cæcum		Lesions in or under incision		Lesions elsewhere in peritoneal cavity			
						Localised			Evidence of spread to general peritoneal cavity
		Abs	Ad	Abs	Ad	Abs	Ad	Obs	
None	1	−	+	−	+	++	++	−	Injection of mesentery of small gut
	2	++	−	−	−	++	+	−	
	3	++	++	++	++	++	+	−	General peritonitis
Intraperitoneal sulphanilamide 300 mg /kg	4	−	+	−	+	−	−	−	None
	5	+	−	+	−	−	−	−	None
	6	−	+	−	−	−	−	−	None
	7	+	+	−	−	−	−	−	None
	8	−	−	+	−	−	−	−	None
	9	−	−	−	−	−	−	−	None
Oral sulphanilamide 300 mg /kg	10	−	++	−	++	++	++	+	Injection of mesentery of small gut
	11	−	++	−	++	++	++	+	
	12	+	+	+	+	++	++	++	General peritonitis

Abs = abscess, Ad = adhesion Obs = obstruction

The only organism which could be grown from the abscesses or from the peritoneal fluid was a pure culture of *Bacillus coli*

CONCLUSIONS FROM SECOND EXPERIMENT

The conclusions which may be drawn from these experiments are —

(1) Liberation of intestinal contents into the peritoneal cavity of a rabbit is followed by the development of a plastic peritonitis, the causative organism of which is the *B coli* It is characterised by abscesses and areas of adhesion of gut to gut and gut to abdominal wall which may produce intestinal obstruction If localisation is poor general peritonitis may result The post-mortem finding in the rabbit exactly parallels the findings at operation or autopsy on patients with peritonitis

(2) The injection of sulphanilamide into the peritoneal cavity at the same time as the contamination with intestinal contents prevents the development of this *peritonitis, the pathological* changes in the rabbits so treated being limited to a localised reaction in the immediate vicinity of the puncture in the gut and the abdominal incision

(3) The administration of sulphanilamide by mouth in one dose of 300 mg per kg body-weight at the time of operation has no effect on the development of this peritonitis

The experiments described deal only with contamination of the peritoneum with gut contents in the absence of intestinal obstruction We have pointed out that if the gut has to be opened at an operation for acute intestinal obstruction the prognosis is very poor, because there is a great probability that a type of fatal peritonitis will develop which is an exact parallel to that we have produced experimentally in the absence of obstruction It seems likely that the prognosis in this type of case may be considerably improved by the use of intraperitoneal sulphanilamide, while the not uncommon complication of an abscess in the wound may be rendered less likely by the use of sulphanilamide implanted in the deeper layers of the incision

THIRD EXPERIMENT

It remained to be seen whether this *B coli* peritonitis did in fact occur frequently after a gut resection in an experimental animal, and if so whether it could be

TREATMENT OF BACTERIAL ENDOCARDITIS WITH HEPARIN AND SULPHAPYRIDINE

By S. Sevitt, M.B., M.Sc. Dubl.

HOUSE PHYSICIAN AND RESIDENT ASSISTANT PATHOLOGIST AT THE GENERAL HOSPITAL, WALSALL

Kelson and White in America (1939) seem to have been the first to suggest and use heparin to reduce the coagulability of the blood in infective endocarditis, their aim being to prevent deposition of fibrin on the vegetations on the heart valves, and thus to deprive the organisms of the defence offered by it; they also suggested the use of sulphapyridine to augment the antibacterial power of the blood. Cases submitted to this treatment have been described by Friedmann and others (1939) in America and by Witts (1940) and Fletcher (1940) in England.

TECHNIQUE

Two cases were treated; in one heparin infusion was given on two occasions. Sulphapyridine was given before the commencement of the heparin infusion in both; in one it was given concurrently with the heparin. Dosage started with 2 g., thereafter 1 g. was given four-hourly for four days, 1 g. four times daily for four days and 1 g. thrice daily for two days. Heparin was employed in the form of Liquemin (Roche) in solution of 5 mg. per c.cm. Blood-coagulation time was measured by the method of Lee and White, as described by Whitby and Britten (1937). The patient's leg was fixed in a Thomas splint, a gold cannula tied into the internal saphenous vein with silk ligature, and the drip infusion started with normal saline. Not more than 1½ litres of fluid was given by the drip per day. The rate of 42 c.cm. per hour can be maintained by regulating a Baxter drip at about 16 drops per minute. The heparin is added in solution to the normal saline in the flask. In this way the number of mg. of heparin per hour can readily be adjusted without altering the rate of the drip, and the clotting-time closely watched; this was observed three or four times during the 24 hours. Heparin, 15–20 mg. per hour, was found to raise the clotting-time to many times its resting value in one case; in the other it only doubled or trebled it. It seems sufficient to raise the clotting-time to half an hour, though some workers recommend an hour or more. The treatment should be carried on for 10–14 days. Among the technical difficulties is that of maintaining a constant slow rate of drip. This may need to be regulated at least every ¼ hour, and for this the coöperation of the nursing staff is essential. Because of its antihæmorrhagic properties vitamin C in the form of ascorbic acid 50 mg. thrice daily was given throughout.

CASE-HISTORIES

Case 1.—A moulder, aged 28, was admitted to hospital on July 9, 1940. He gave a history of influenza three weeks previously and being in bed since, with weakness, malaise and sweating particularly at night; past illnesses included "rheumatics" at 15 years and 3–5 attacks of influenza. He was pale, with a peculiar yellow tinge in his face; skin warm and moist; rather wasted; temperature 100.5° F.; pulse-rate 120, regular, Corrigan type; clubbing of fingers with increased curvature of nails. On July 10 his urine contained albumin and urobilin, a few pus cells and red cells; no organisms. On July 12 he was seen to have petechiæ under the nails and on the abdomen; intermittent temperature between 98° and 102° F. Spleen not palpable, but splenic dullness increased in area. Heart enlarged to the left; localised presystolic mitral murmur, and pulmonary second sound accentuated. Blood-pressure 130/70. The second sound soon became reduplicated in the mitral area and later a diastolic murmur appeared outside the apex-beat. On the 22nd his presystolic murmur had spread towards the tricuspid valve and there was an added systolic murmur at the apex. Blood count on July 12 gave red cells 3,200,000; Hb. 56%; white cells 18,600; polymorphs 82%. Blood-cultures on July 10 and 15 gave short chained gram positive streptococci showing neither α nor β hæmolysis.

A ten-day course of sulphapyridine was begun on July 15; his temperature came down and remained below 99° F. until the 22nd. Pulse varied between 80 and 120, averaging about 100. On July 19 blood-culture was still positive. A course of ascorbic acid was begun on July 22, and the intravenous heparin drip set up. Blood-coagulation time before this treatment was 5¾ min. In the first 24 hours he received 1 litre of saline, and about 230 mg. heparin (about 10 mg. per hour). Blood-coagulation varied between 6 and 6½ min. The temperature rose to between 100° and 101° F. on the 22nd, and next day to 104.3° F.; pulse-rate rose to 160 and he developed a dry, painful, irritating cough with pain in right chest. A pulmonary embolism was diagnosed, but in spite of this the treatment was continued, and in the next 18 hours about 360 mg. of heparin was given (about 20 mg. per hour). The clotting time rose to 8½ min. and later to 10 min. On the morning of the 24th the patient was seized with acute œdema of the lungs and died.

Autopsy.—Numerous white infarcts in spleen and kidneys. No microscopic evidence of nephritis. Embolus in right pulmonary artery and severe œdema of right lung; microscopically, the lungs showed œdema and heart-failure cells. Brain normal. Liver friable and brownish-yellow; microscopically, the liver cells were degenerate and the whole liver infiltrated with round cells, largely periportal in distribution. Heart showed vegetations on mitral and tricuspid valves; mitral valve stenosed. Vegetations small, brownish and friable, and not abundant; microscopically, fibrosis at base of vegetations, some fibrin on the surface; no organisms seen. Urine: no red cells or casts; film showed scanty streptococci.

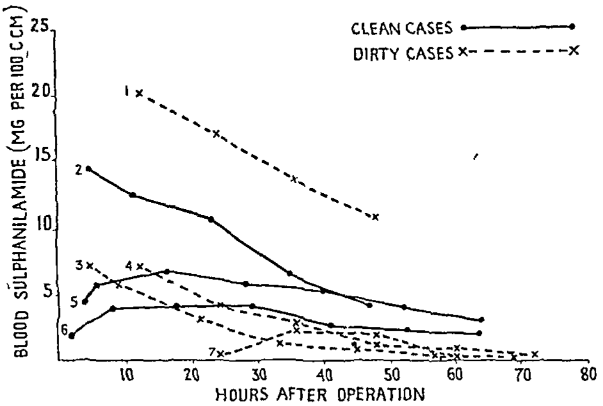
Case 2.—A man admitted on June 15, 1940, complaining of tiredness, malaise and sweats. He gave a history of "influenza" in March with lassitude and pains in the legs, and was in bed for a month. Returned to work (as a turner) for a week but had not been well since. Before admission had œdema of his ankles but no dyspnœa. He was a well-built man but had recently lost weight; yellowish tinge to skin; no Osler's nodes; no clubbing of fingers. Slight œdema of ankles present which soon disappeared. Purpuric spots on legs which faded in a week. The temperature irregularly intermittent from 97°–99° F. to 100°–102° F. Pulse-rate varied between 80 and 100; regular, full and collapsing. Liver and spleen never palpable. On July 2 he had a sudden severe attack of pain over the splenic area and a friction rub developed. The heart was normal in size. At first there was a loud systolic murmur at the apex transmitted outwards and the pulmonary second sound was accentuated. On June 27 a localised mitral presystolic murmur was added and later this became generalised. Urine: heavy albuminuria every day; film showed numerous casts and red cells; deposit contained streptococci, hyaline and granular casts. Blood-urea 50 mg. per 100 c.cm.; urea clearance low normal. Blood-picture showed a slowly progressive normochromic anæmia, and a polymorphonuclear leucocytosis. Blood-culture: several positive cultures obtained of a gram positive non-capsulated, non motile, short-chain streptococcus giving neither α nor β hæmolysis on blood-agar.

On July 3 a ten-day course of sulphapyridine was begun. Within 24 hours the temperature was normal, but on the night of the 10th it rose to 102.2° F. Blood-culture was positive on July 4; on the 11th a course of vitamin C was begun. The intravenous heparin drip was set up on July 12; clotting-time then 4½ min. In the first 20 hours patient received less than ¾ pint of saline and 100–120 mg. heparin (5–6 mg. per hour). The clotting time was 9, 10 and 9½ min. at various times that day. The rate of the drip was then doubled, giving about 1 litre of saline in the next 24 hours, and 10–12 mg. heparin per hour. As the clotting time was still only 10 min. the heparin was increased to 16 mg. per hour in the evening of the second day. This rate was maintained for the next 36 hours, and on July 14 clotting-time was longer than 5 hours. All this time the patient appeared better, with a pulse rate between 80 and 100. The first two days his temperature was normal; on the third day it rose to 101° F., and on the fourth he had a rigor and it went up to 103° F. Soon air-hunger developed, then coma and in 2–3 hours a left hemiplegia was found. Treatment was discontinued after 72 hours. The patient regained consciousness, but developed œdema of his ankles. This increased and spread to legs, face and back. Urine still contained red cells and streptococci. The hemiplegia gradually passed away, and by July 30 muscular power was almost normal, but the mitral presystolic murmur became diffuse and pulse-rate averaged 100. The intravenous heparin drip was recommenced on July 31 and sulphapyridine given concurrently. Vitamin C was given as before. Blood-coagulation time before treatment was 3 min.

back pressure from secondaries in the liver, and at autopsy the line of anastomosis was already nearly invisible and there was no evidence of past or present peritonitis or adhesion

CASE 2 —A woman of 62 was admitted with a strangulated femoral hernia of 30 hours' duration, vomiting, distended, but with only moderate signs of toxæmia Operation (R S) disclosed 2 in of gangrenous terminal ileum Resection and side to side anastomosis with a proximal ileostomy were performed through a paramedian incision and 15 g of sulphanilamide was inserted, 5 g powdered around the anastomosis and ileostomy, 2 g into the deeper layers of the wounds, and 8 g suspended in saline in the peritoneal cavity Postoperatively, continuous gastric suction was again employed, and a high concentration of blood sulphanilamide was maintained by the postoperative administration first into an intravenous drip and later by intramuscular injection of sulphapyridine After 8 days the physical signs, the fluid balance chart, and straight radiography showed that there was no hold up at the anastomosis or elsewhere, and the ileostomy drainage for 24 hours diminished to 3 oz Gastric suction was stopped and the ileostomy tube was removed The patient was transferred to a convalescent home with both wounds firmly healed 13 days after operation

It is unwise to draw conclusions from only 2 cases, but we do feel that it is encouraging that the first patients treated with intraperitoneal sulphanilamide should escape completely the peritonitis which we know is so common



Sulphanilamide, used as described above, constitutes a prophylactic but not a therapeutic measure We do not yet know whether or not it can have a therapeutic action in cases of established peritonitis We have, however, used intraperitoneal sulphanilamide in a number of cases other than acute obstruction with the object both of assessing a possible therapeutic value and of investigating the effect on the concentration in the blood of sulphanilamide The following cases were treated by the injection of sulphanilamide into the peritoneal cavity at the conclusion of operation —

1 Pancreatic abscess, drained by a tube through the gastro colic omentum and traversing the peritoneal cavity (organism, *B coli*)

2 Perforated appendix with free pus in the peritoneal cavity (organism, *B coli*)

3 Appendix abscess, poorly localised, with free pus in the peritoneal cavity (organism *B coli*)

4 Perforated gastric ulcer of 19 hours' duration, with considerable contamination of the peritoneum by gastric contents

Uneventful recovery followed in 3 cases The patient with the pancreatic abscess died, this was not remarkable since prior to surgery she was also contending with portal pyæmia, diabetic coma with renal failure, and bilateral bronchopneumonia, at autopsy she was found to have severe mitral stenosis In each case the blood sulphanilamide was estimated after the operation at intervals up to 72 hours

In order to compare the rate of absorption from normal peritoneum, sulphanilamide was introduced at operation into the peritoneal cavity in the following clean cases —

1 Strangulated hernia without gangrene

2 Partial gastrectomy

3 Cholecystectomy

The dose in every case except one was 10 g suspended in saline, the case with the pancreatic abscess was given 15 g The figure shows the levels of blood sulphanilamide in these 7 cases from the time of operation up to 72 hours The rate of absorption varied considerably from case to case, but there was no obvious difference between the absorption in clean and contaminated cases

SUMMARY

Analysis of 670 consecutive cases of acute intestinal obstruction showed that the fatality-rate in cases where simple release could be practised was 6 7%, whereas the rate was 77 4% when resection was necessary

The high fatality in cases in which the gut has to be opened, whether for resection, anastomosis or enterostomy, is mainly attributed to a postoperative plastic peritonitis leading to mechanical obstruction

The causative organism of this plastic peritonitis is the *B coli* and the peritoneum is infected by contamination with gut contents when the gut is opened at operation

Experiments with rabbits demonstrated (1) that sulphanilamide introduced into the peritoneal cavity was well absorbed and caused no local inflammatory reaction, (2) that contamination of the peritoneal cavity with contents of the cæcum produced a plastic peritonitis with the formation of abscesses and adhesions, and sometimes general peritonitis, (3) that this plastic peritonitis could be prevented by introducing sulphanilamide into the peritoneal cavity at the time of the contamination, but not by a single large dose of sulphanilamide given at that time by mouth

Further experiments with rabbits showed (4) that *B coli* peritonitis followed resection of gut with great regularity, (5) that prophylactic use of intraperitoneal sulphanilamide usually reduced, and in some cases even eliminated, the inflammatory process, but (6) that in the presence of a fulminating infection intraperitoneal sulphanilamide in the doses which we employed was valueless

So far 2 cases of resection of gut for acute intestinal obstruction in man have been treated with intraperitoneal sulphanilamide In neither of these was there any postoperative obstruction or peritonitis, local or general

Our thanks are due to Prof James McIntosh for providing us with the facilities to carry out these experiments in the Bland Sutton Institute of the Middlesex Hospital, as well as for his counsel and interest

PRESERVATION OF BLOOD FOR SUGAR ANALYSIS

BY R D LAWRENCE, M D Aberd, F R C P
PHYSICIAN WITH CHARGE OF THE DIABETIC DEPARTMENT, KING'S COLLEGE HOSPITAL

Dr E J King and his colleagues have lately described a simple method for preventing glycolysis (*Lancet*, March 8, 1941, p 310) For those who use the common Folin-Wu method or modifications the following is of interest and value as preservation is ensured without any extra solutions or manipulations After the collection of 0 1 or 0 2 ml of blood into water and the usual precipitation of proteins by 2/3N H_2SO_4 and 10% sodium tungstate, the resultant mixture can be left safely up to a week at room temperature without any change in sugar content, which is often very convenient in war-time delays The following figures show this

	Sugar mg per 100 ml in	
Days	Sample 1	Sample 2
1	218	69
3	206	72
5	215	72
7	206	61

These figures show minor variations of no practical magnitude which are due to war-time difficulties with heating apparatus I have found that the preservation of sugar in whole blood by fluoride is shorter and lasts only 2–3 days

I wish to express my thanks to Mr H R Millar for these estimations

were estimated twice daily, subsequently they were estimated daily These clotting times and the dosage of heparin for each period between estimations are given in the table It will be seen that the clotting time remained at or above four times its normal value except on the 5th day, when the vein through which the heparin was being given became occluded and the infusion was stopped for a few hours On the 12th day the patient complained of slight headache and mistiness of vision in the left eye The next day this was worse, and on the morning of the 14th day she rapidly became comatose and died The heparin infusion was stopped 6 hours before death Throughout the period of treatment the patient's temperature swung between 99° and 101° F There were no rigors

Date in Dec 1940	Dose of heparin (mg per hr)	Clotting time (min)	Date in Dec 1940	Dose of heparin (mg per hr)	Clotting time (min)
3		6¼	9	8 3	9
4		6¼	10	7	28
5 A M.	4	8¼	11	7 8	25
5 P M	8	28	12	13	48
6 A M	10	77	13	13	50
6 P M	10	50	14	10	31
7	6 7	55	16	11 3	50
8	9 2	31	17	12 5	51

At autopsy there were small bilateral pleural effusions, the lungs were œdematous with some hypostatic pneumonia There was a small pericardial effusion, the heart weighed 390 g and was dilated on the right side There was slight stenosis of the tricuspid valve with no vegetations, the mitral orifice was narrowed by old rheumatic infection There were numerous large friable vegetations on the valve surface, the chordæ, and the wall of the left auricle The left ventricle and aortic valves showed no change The spleen weighed 616 g and showed old and recent infarcts The kidneys contained a number of old infarcts The brain showed an extensive subdural hæmorrhage on the right side, evidence of old subarachnoid hæmorrhage, and a mass of blood clot exuding from the right occipital pole which arose from a hæmorrhagic cavity in the white matter There were also a few cortical hæmorrhages in this region There were no other gross abnormalities

Microscopically, the mitral valve and auricular endocardium presented the typical appearances of subacute bacterial endocarditis and differed in no recognisable way from those seen in untreated cases There was evidence of old rheumatic scarring in the myocardium and valves The mitral valve was vascularised, and on the auricular surface near the point of closure there were bacterial vegetations covered with a fibrin thrombus and lying on a granulation-tissue base Much of the fibrin appeared to be of recent deposition In the brain, near the hæmorrhage, there was considerable proliferation of the capillary endothelium, and ring hæmorrhages but no thrombi were detected

SUMMARY

Heparin treatment of subacute infective endocarditis carries with it a risk of cerebral and other vascular accidents

A case is reported in which heparinisation was adequately maintained for 14 days, the patient then dying of cerebral hæmorrhage

At autopsy the vegetations in the heart were in no way different from those seen in untreated cases There were recent depositions of fibrin and no signs of healing It may be concluded that the heparin treatment of subacute bacterial endocarditis is both dangerous and ineffective

I wish to thank Prof L J Witts for his advice and his permission to publish this case, and Dr A H T Robb Smith for his report of the autopsy

CALCIFICATION IN MUSCLES OF FOREARM

By **Ralph Shackman**, M B Lond, F R C S
SURGEON, MINISTRY OF PENSIONS WAR EMERGENCY SCHEME, FIRST ASSISTANT IN THE DEPARTMENT OF SURGERY, BRITISH POSTGRADUATE MEDICAL SCHOOL, AND

C J Longland, M B Lond, F R C S
JUNIOR SURGEON, MINISTRY OF PENSIONS SCHEME

In October, 1917, a patient sustained a severe gunshot wound of the right upper arm, much of the deltoid muscle was torn away and the humerus was fractured at this level He was lying out in the field for two days before he was brought to a casualty clearing station where the wound was cleaned up, the arm splinted on a hinged wooden elbow-splint with the elbow flexed to 90°, and the arm bandaged to the side of the chest After about a week an operation was carried out on the wound, and a plaster was applied from the knuckles to the middle of the upper arm, with the elbow flexed to a right angle This plaster was applied (the patient says) because the wrist had dropped during the week immediately following the accident He remembered no pain, swelling or numbness of the forearm or hand but, as he says, he was so ill during the first week that the statement has little value The gunshot wound became infected and two years later was still discharging pus, while the patient himself showed evidence of amyloid disease By the end of the third year the wound had healed satisfactorily with union of the humerus, shoulder movements were improving, elbow movements were returning, but pronation and supination of the forearm were almost absent and the wrist was fixed in flexion Some finger movements were possible In 1922 the electrical reactions showed no response to faradic stimulation of the dorsal interosseous nerve, but the median and ulnar nerves responded normally A radiogram of the wrist showed no abnormality

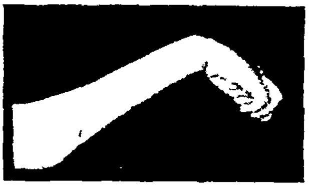

FIG 1—Position of wrist and fingers

We saw him in July, 1940, when he was a healthy man, aged 47 years, working as a cycle engineer He complained of a recent attack of pain in the right forearm The scar of the upper arm was soundly healed and was not tender or abnormal The forearm was considerably wasted, and the skin of the back of the wrist and hand was thin and shiny The shoulder could be abducted against gravity to beyond a right angle despite great loss of the deltoid muscle The elbow could be flexed and extended powerfully over a range of 45° to 135° The forearm was held in a position midway between supination and pronation, and only about 10° of supination was possible Some small hard nodules were felt among the wasted muscles of the forearm, but the majority of the calcified tissue shown in a radiogram was impalpable The brachio-radialis muscle acted powerfully The wrist was held flexed at 80° (fig 1) and could be further flexed passively for a few degrees No extension of the wrist was possible All metacarpophalangeal joints were extended and held straight except the fourth, which was hyperextended The interphalangeal joints were all flexed The middle finger was strongly flexed The thumb was held straight and adducted Slight active flexion of all the fingers was possible and the forearm muscles could be seen contracting when this was carried out No extension of the fingers was possible, and no flexion or extension of the thumb Adduction and abduction were present in the fingers There was no anæsthesia to light touch in the forearm and hand The radial, brachial and axillary arteries pulsated normally, but the right hand was obviously colder than the left and its temperature was 22° C as opposed to 29° C of the left hand (room temperature 14° C) Faradic stimulation of the median and ulnar nerves at the elbow gave normal reactions in the flexor muscles, but there was no response to faradic stimulation of the posterior interosseous nerve

The drip was begun at 10 mg in 42 c cm of saline per hour Two hours later the temperature rose from 101° to 104° F and the patient had a rigor lasting an hour The clotting-time varied between 9, 11½ and 9½ min that day, the temperature remained up at 102° F Next day the patient seemed better, and his facial œdema disappeared The coagulation-time remained at about 10 min that day, and the heparin was then increased to 20 mg per hour His urine still contained red cells and streptococci Blood count red cells 2,200,000, Hb 40% Blood transfusion of 1 pint was given the next day The clotting time was then 21½ min, patient was visibly improving, presystolic murmur again localised, blood-culture still positive, heparin maintained at 20 mg per hour On Aug 3 condition the same, but the clotting time fell to 10 min and later rose to 14 min That evening there was a sudden change, coma came on rapidly, eyelids and right arm twitched and he died later that night The course of treatment lasted 80 hours

Autopsy —Heart of normal size, fibrous stenosis of mitral valve Small brownish vegetations attached to cusps on ventricular surface near free border of valves also attached to chordæ tendineæ, but endocardium not involved, and major area of valves free Microscopically, vegetations showed fibrosis at their bases, some fibrin near surface, and numerous streptococci in deeper layers of fibrin Lungs free fluid in both pleural sacs, pulmonary œdema and brown induration present, microscopically, alveolar walls congested and alveolar spaces full in many places with red cells and heart failure cells Liver normal in size, colour and consistence, microscopically, cloudy swelling and degeneration of liver cells with some leucocytic and round cell infiltration between liver cells Spleen enlarged to three times normal size, two large, white infarcts near surface, microscopically, congested otherwise structure normal Kidneys, both enlarged and somewhat pale; typically "flea bitten", microscopically, diffuse glomerulonephritis showing glomeruli in subacute and chronic stages of inflammation, but none in acute hæmorrhagic stage, in the lumina of tubules red cells present, and in others hyaline casts Brain large area of softening involving under surface of right occipital lobe, superior temporal lobe, and internal capsule, no hæmorrhage, no embolus found, microscopically, degenerated area infiltrated with pus cells and round cells near cortical surface

DISCUSSION

Outstanding features of these two cases are the deaths of both patients from embolism, in one pulmonary and the other cerebral, the rapid clinical improvement in case 2 during both courses of treatment before the embolism, and the appearance of the valvular vegetations, which were much smaller than is usual and contained less fibrin In case 1 no organisms were seen microscopically on the vegetations Neither case underwent a full 10–14 day course of treatment, had this been possible the results might have been different The treatment is undoubtedly highly dangerous, Kelson and White, and Witts and Fletcher have reported cerebral accidents similar to those in the two cases reported here The treatment nevertheless seems justifiable for what is invariably a fatal disease

I wish to thank Dr S C Dyke and Dr M B Baines for permission to publish these cases Dr Dyke also helped me in the treatment of the cases and in drawing up this report

SENSITIVITY TO CARROTS —Now that carrots are to take a more prominent place in our dietary, whether as a vegetable or as a diluent for marmalade, we may hear more of them as an occupational hazard H R Vickers (*Brit J Derm* February, 1941, p 52) reports seven cases of dermatitis in girls employed in the canning of carrots Sensitisation did not develop until they had been handling raw carrots for some time Vickers did not identify the responsible constituent, but he decided that it was not the essential oil Thus another substance has been added to the ever-growing list of skin sensitisers

---

FAILURE OF HEPARIN IN SUBACUTE BACTERIAL ENDOCARDITIS

BY C M FLETCHER, M B Camb
NUFFIELD RESEARCH STUDENT AT THE RADCLIFFE INFIRMARY, OXFORD

SINCE Kelson and White (1939) first described the treatment of subacute bacterial endocarditis with sulphapyridine and heparin several other cases treated by their method have been recorded

Witts (1940), Fletcher (1940) and Miller (1940) have reported cases which died of cerebral hæmorrhage during the treatment Petch (1940) reported 2 such cases and 1 dying of toxic jaundice Sevitt (1941) treated 2 cases which died of embolism (pulmonary and cerebral) during the treatment Klieber (1940) reported a case in which treatment had to be stopped owing to hæmaturia The only successful cases were 1 of Petch's (well for six months) and 1 of Weeks's (1940), but in the latter the diagnosis was not proved Thus it is clear that treatment with heparin carries with it a serious risk of cerebral and other vascular accidents, and it was in view of this that I suggested (Fletcher 1940) that it should only be given to cases in which there were no embolic signs

Swain (1940) suggested that, before heparinisation is embarked on, the infecting organism should be shown to be susceptible to chemotherapy in vitro If, however, heparin acts in the way postulated by Kelson and White it should be effective in the absence of sulphapyridine, for the blood of patients suffering from subacute bacterial endocarditis is known to be rich in antibodies to the infecting organism, if heparin can abolish the bacterial breeding ground the patient's blood should be capable of dealing with the circulating bacteria The essential question is whether heparin, given intravenously for 14 days in dosage sufficient to prolong the clotting time by four or five times its usual length, does or does not inhibit the formation of vegetations on the valves of the heart This information has been provided recently by a case treated with heparin alone, in which the patient died on the 14th day of heparinisation It was thus possible to observe the valves at the completion of treatment

CASE-HISTORY

A housewife, aged 40, had had rheumatic heart disease in childhood She had coryza and a dental extraction 4 months before admission and since that time had felt unwell, 3 months before admission she found herself feverish At this time she noticed painful spots at the tips of her fingers for a few days, became breathless on slight exertion, and had some swelling of her ankles From that time until her admission she remained in bed, being continuously febrile but not feeling particularly unwell

When examined on Nov 19, 1940, she was pale and slightly sallow She had many flat pigmented spots all over her body, some of which she said had been present since childhood, but some she thought had appeared since her present illness No recent petechiæ were seen on this or any subsequent occasion There was clubbing of the fingers and a palpable spleen Cardiac enlargement was moderate, murmurs indicating mitral stenosis and aortic regurgitation were present Blood count red cells 3,130,000, Hb 60%, white cells 5800 No red cells were found in the urine Blood culture showed a *Streptococcus viridans*, this organism was tested for susceptibility to sulphapyridine and sulphathiazole by Mr R L Vollum, D Phil, who found that it grew readily in blood when a concentration of 50 mg per 100 c cm of either substance was present

In view of her good general condition and absence of embolic signs the patient was considered to be suitable for heparin therapy Since her infecting organism was not susceptible to chemotherapy it was decided to try heparin alone Liquemin (Roche) was used The powder was dissolved in normal saline in a strength of 1 mg per c cm This standard solution was then diluted with normal saline for the actual infusion according to the needs of the patient The total volume of saline given daily was restricted to 1 litre The infusion was started on Dec 4 and was continued for 14 days Throughout this period 300 mg of ascorbic acid was given daily after an initial course of 1000 mg daily for 3 days For the first 2 days clotting times (Lee and White) further increased doses were given until the result was obtained (e g 0 2 sec at 135 volts, then 0 25 sec at 135 volts, then 0 25 sec at 140 volts and so on)

A sub-threshold shock raises the threshold to a subsequent one so that the true threshold, after a series of unsuccessful stimuli, is slightly lower than would seem likely from the effective setting After the first determination of threshold the patient becomes slightly more fit-resistant each day, as with Cardiazol, but, as the curves show, the rise is slight and is most definite during the first few days In several hundred other patients there was no continuous rise of threshold

In the curves of fig 1 the ordinate is the product of voltage and duration It has been found that on the whole, the cerebral-excitability curve for convulsions shows a constant quantity relation, if the duration is halved the current must be doubled to have the same effect, so that if in a series of test stimuli both time and strength are varied the product of the two can be regarded as a suitable quantity for plotting The electrical resistance of each patient varies little from day to day so that the current was roughly proportional to the voltage Moreover, resistance variations are mostly illusory, since the skin resistance, which provides nearly the whole of the measured resistance, disappears altogether with the strong current used to induce the convulsion Measurement of the brief stimulating current itself is unreliable, since the power factor is uncertain, measurements with cathode-ray indicators have shown that the actual current passing can be assessed accurately by assuming in any given patient a proportionality with voltage

The nature of the convulsion and of the recovery stages were noted on each occasion On the 16th, 17th and 18th days three capsules of epanutin were given by mouth As the curves show, the effect on the convulsion threshold was not visible for several days Possible reasons for this delayed action and its clinical significance will be discussed later The effect of the epanutin on the patients' mental state and on recovery from the convulsions cannot usefully be discussed until more observations have been made over a longer time The cases selected for these preliminary trials were not of a type to give a very clear account of their feelings This paper is concerned rather with the effect of the drug on the convulsive process and with the clinical inferences that can be drawn

After the few days' latency the threshold rose considerably in all patients In two of them the rise was so great that it became impossible to induce a convulsion at all This is striking objective evidence of the protective power of the drug A second series of doses was given on the 21st, 22nd and 23rd days This time six capsules were taken every day, and after a few days they caused a second hump in the curves, but the effect was little greater than after the smaller doses After this second peak the decline in threshold was very slow and irregular, some of the patients taking 14 days to return to the pre-dosage level During the height of the drug-action period it was noticed that the convulsions in all patients were more ragged and variable in duration than usual, the tonic stage was often particularly abbreviated Recovery was usually more rapid and mental confusion seemed less frequent Two patients seemed intoxicated by the drug and one of them babbled incoherently, but there were only mild physical signs of epanutin intoxication

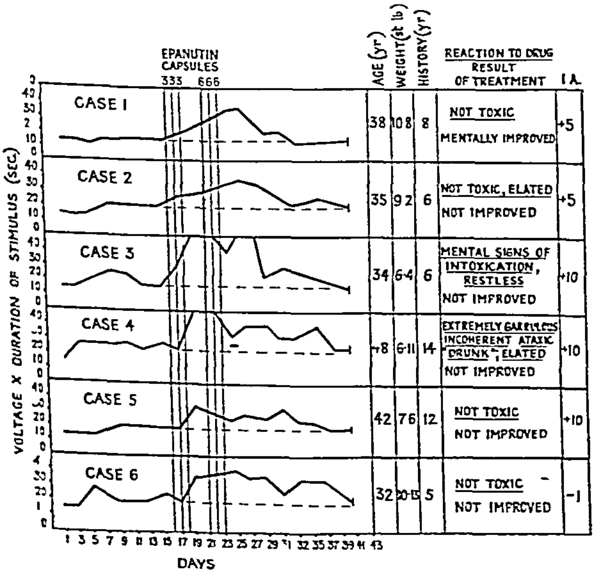

FIG 1—First trial showing variation in threshold produced by epanutin Voltage and duration of stimulus were varied to obtain a threshold. I.A., impedance angle

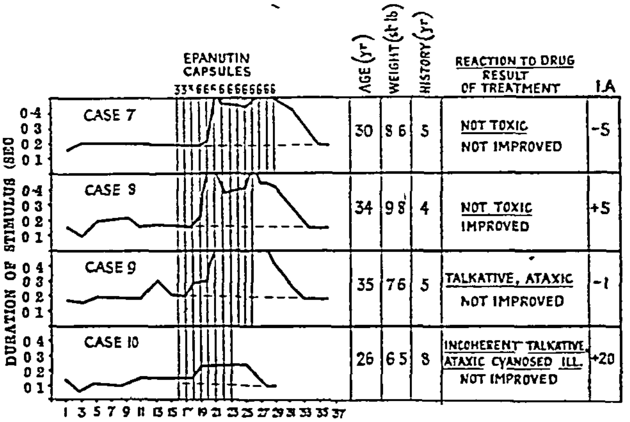

FIG 2—Second trial Voltage was kept constant except when threshold became extremely high

SECOND TRIAL

A second series of four patients also undergoing electric-convulsion therapy was then selected for a further trial They were of the same type as those in the previous group

In these cases the voltage was kept constant, only the duration was varied, except when the threshold became extremely high and the maximum dosage was administered to prove complete resistance to convulsions Fig 2 shows the duration threshold changes, together with the physical features and responses of the patients As in the previous series, there is a definite latency followed by a sharp and dramatic rise Administration of epanutin was begun on the 16th day with three capsules daily, and from this day convulsions were given daily in order to observe the detail of the threshold changes On the 19th day dosage was increased to six capsules daily and was continued for the varying periods shown on the curves Again two of the patients became completely resistant to fits, one showed a 100% rise in threshold and the one with the poorest physique only a 50% increase This patient also exhibited severe toxic symptoms—ataxia, increased cyanosis and confusion—and the drug was withheld on the 23rd day. In the other patients withdrawal was followed by a decline in threshold which reached the pre-dosage level in 4–7 days In the first series the fall was much slower and it is tempting to explain this difference as an effect of the more frequent convulsions In the second series the day-to-day fall in threshold after withdrawal was more rapid, but the decline after each convulsion was about the same as in the first series

DISCUSSION

As the curves clearly show, the convulsion threshold was significantly raised in all the patients In the smaller patients the rise was so great that no convulsion could be induced, nor in these cases was there any sign of cortical spread or persistence suggestive of an abortive epileptic process This confirms the claims of Putnam and Merritt regarding the dramatic effects of the drug on animals The other striking point is the delayed action of the drug There is a latent period of 4–6 days, after which the effect develops rapidly to its maximum On withdrawal there is an almost immediate but gradual decline, varying in rate apparently with the number of

The patient thus had a partial radial-nerve lesion affecting the forearm extensor muscles The forearm muscles of the flexor group were contracted and wasted but their nerve-supply was intact The radiogram (fig 2) shows that the muscle bellies of the flexor and extensor aspects of the forearm are infiltrated by calcium deposits which give an approximate rendering of the size and shape of the extensor indicis proprius, extensor pollicis longus and brevis, while other deposits are to be seen in the flexor digitorum profundus, flexor pollicis longus and in the radial extensors of the wrist These deposits are apparently extra-periosteal Radiograms of the upper arm and hand showed a united fracture of the humerus and disuse atrophy of the bones of the hand

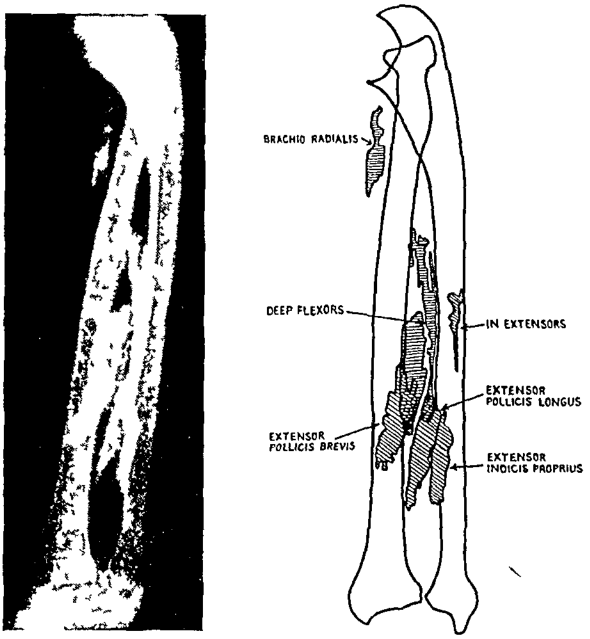

FIG 2—Anteroposterior radiogram of forearm, with key

DISCUSSION

The most arresting feature of this case is the widespread deposition of calcium in the forearm muscles The conformation of the deposits in the thumb extensors shows that the muscle-fibres have been largely replaced by calcium, and by analogy it is probable that the more irregular deposits have also originated in muscle The paralysis of the dorsal interosseous nerve may represent a partial nerve lesion occurring at the level of the wound, or more probably an unusual sequel of an ischæmic paralysis of the Volkmann type That such an ischæmia occurred is probable from the history and present condition of the limb, and it was doubtless due to some injury of the brachial artery The distribution of the calcium deposits indicates that both flexor and extensor groups were affected by the ischæmia Calcification of muscle after pure nerve injuries sustained in the last war was described by French writers and more recently by Voss,[1] but a radial-nerve lesion alone cannot be held responsible for the widespread deposits in this case This ischæmic involvement of the extensor group differs from the usual account of Volkmann's contracture in which there is described a contracture of the flexors only The extended posture of the metacarpo-phalangeal joints indicates that the extensors were affected by the ischæmia

This case is an example of dystrophic calcification such as is found in old tuberculous glands, scars and other unabsorbed devitalised tissue, the muscle devitalised by ischæmia would also seem to be a likely site for the laying down of calcium

We wish to thank Dr Herbert Lightstone, director general of medical services, Ministry of Pensions, for permission to record this case

EPANUTIN AND ELECTRIC CONVULSION THERAPY

BY

R E HEMPHILL, M D DUBL, D P M
W GREY WALTER, M A CAMB

(*Bristol Mental Hospital and Burden Neurological Institute, Bristol*)

THE anti-convulsant properties of disodium diphenyl hydantoinate (Epanutin) were discovered experimentally by Putnam and Merritt (1938), who found that it remarkably raised the threshold for electrically induced fits in animals The rise was often of the order of 100% or more while the effect of Luminal and bromide was much less striking

Encouraged by these discoveries Merritt and Putnam (1939) tested the drug on epileptic patients and found a very satisfactory reduction both of major and of minor attacks even in patients who had been unresponsive to luminal At the same time there was little or no hypnotic or depressant action, though in certain cases there were troublesome side-effects The drug is now accepted as a valuable addition to our armoury against epilepsy The pharmacology of the compound is still incomplete and the nature of its anticonvulsant action is quite obscure Although resembling the barbiturates slightly in composition its action seems very different since it is not a cerebral sedative, and, from electroencephalographic studies, it seems to affect the local epileptic abnormality rather than the tendency of the disturbance to spread over the cortex which appears to be the basis of action of luminal

Acting on the suggestion of Dr F L Golla that epanutin might act through improvement of the cerebral circulation, it was decided to try the effect of administering the drug to a series of patients suffering from a variety of mental disorders There seemed a possibility that normal cortical function might be encouraged even in patients not liable to typical epileptic attacks The results were irregular but not altogether unpromising Pushing the dosage evoked side-effects, and the treatment was discontinued At the same time a number of similar patients were being treated with convulsions induced by brief electrical stimuli, for accounts of the technique see Cerletti and Bini 1935, Golla, Fleming and Walter 1939, 1940, Shepley and MacGregor 1939, 1940, Walter 1940, Fox 1940 There seemed a possibility that a combination of this treatment with small doses of epanutin might produce good results Moreover, although the results of the electrical treatment are excellent and accidents few, there are occasional mildly unpleasant transitory sequels, such as poorness of memory and orientation and sometimes considerable confusion Since epanutin often has an excellent effect upon similar complaints in epileptics, it was decided to try the effect of the drug on patients undergoing electric convulsion therapy It was known, of course, that the electric convulsion threshold was likely to be raised by this procedure, but the margin of safety in the electrical treatment is so great that dangerous consequences were not anticipated, even if twice the usual dose of current had to be given As it turned out, this confidence was justified

FIRST TRIAL

A group of six patients was selected for the first trial They were all chronic schizophrenics with some degree of dementia and of fair physical condition None presented any distinctive clinical features Their respective ages, weights and lengths of history are given in fig 1, which also shows the variation of threshold during and after the period of epanutin dosage It will be seen that treatment was given three times a week

In this series both voltage and duration of stimulus were varied to obtain a threshold The voltage was set to an average value, usually 130 volts The time switch was then adjusted to a fairly short duration, usually 0 2 sec If a convulsion resulted immediately without latency the dosage was reduced slightly on the next occasion—for example, duration dropped to 0 15 sec If there was a definite latency of more than 3 sec the dose was taken as threshold and the same was given next time If there was no convulsion

35%, appendicitis for 2·3% and cholecystitis for 0·8%. The last two figures agree closely with those of the Mayo Clinic. According to C. E. Newman, 92% of Army dyspeptics had symptoms before joining, and a more recent examination of recruits by Colonel J. Gibson Graham indicated that 94% of patients with peptic ulcer previously had symptoms of an average duration of seven years; in the more shadowy group of gastritis 80% had a previous history averaging nine years. Little attention has been paid to the large increase in dyspepsia in the civilian population during the last twenty years. Army rations are undoubtedly heavier than those to which most recruits have been accustomed as civilians, but considering the small amount of organic disease that begins in the Army and the remarkable health of the men in the training centres, it can be said that the Army diet is entirely satisfactory for healthy men who have not previously suffered from dyspepsia. The cooking, though it left much to be desired in earlier days, has improved out of all knowledge. These men would have relapsed just as certainly, though possibly a little later, on the best diet and cooking. Army routine is not compatible with the maintenance of health in chronic dyspeptics. A busman can take many light meals throughout the day—practically a Sippy diet. But in the Army, even in peace-time, a man with a peptic ulcer cannot live the routine life, and a regulation has for many years been in force that men with organic lesions or peptic ulcers shall be invalided. Those who have recently advocated the invaliding of all peptic ulcer cases have forgotten that this is the ordinary practice.

Many men who report sick with dyspeptic symptoms are classed as psychoneurotic and sent to psychiatrists and psychiatric wards. These have not been included in the medical returns as dyspeptic. If psychological factors are not often found in the medical ward, the exclusion of these cases is the reason. Newman, and also Graham, concluded that there is very little psychological disturbance in peptic ulcer and similar conditions. Peptic ulcer cases in hospital lose their symptoms purely on rest and dietetic treatment; psychological disturbances—unless they were gross—do not delay recovery.

The findings in gastritis cases are negative on admission. They correspond largely to the cases seen in outpatient departments who are investigated fully without any cause being found and are then sent back to their doctor. In the Army such patients have to go into hospital. The gastroscope might advance knowledge of them, but the Army does not provide gastroscopes. These cases cannot be dealt with by short courses of treatment. They are far more resistant than peptic ulcer cases and have far more of a "psychological aura." They should be sent back to their units. In the earlier months it was the practice to mark them down to lower categories, but that course completely failed; they relapsed and their symptoms continued just as definitely. They are capable of carrying on in spite of their discomforts and of making useful and efficient soldiers. It is the duty of medical officers to keep them in their units as long as possible; but when they have been twice in hospital it is useless to start them on a shuttle-service, and they should be boarded out.

Transient dyspepsia is nearly always discussed in terms of cases in hospital. The cases which never get there are far more numerous. A healthy man may report sick with dyspepsia during the second fortnight in his training centre, and a wise medical officer will reassure him and give him a bottle of medicine to avert the stigma of malingering. The man may report sick twice more in the next fortnight, perhaps once in the next, and then he becomes acclimatised. A weak medical officer would send such a patient to see a physician in hospital or a medical specialist. A good specialist would send him back with a strong hint not to refer such cases; but if he has had too much experience of consulting practice he will admit the man to hospital, where he will be fully examined with negative results, rapidly lose his symptoms and be discharged "cured." If a man comes into hospital twice for the same complaint he is unlikely to develop into a useful soldier; he has been converted into a case of incurable gastritis. Special hospitals, though they may offer the advantage of research, are not to be recommended for gastric cases; the work in the smaller hospitals has reached a very high standard.

Dr C. E. NEWMAN described the investigation he undertook with Mr R. T. Payne early in the war. The Army then consisted largely of old reservists and was faced with the dietetic problems of an expeditionary force. Later investigations, however, showed that organic lesions bulked large. Another group consisted of men with "gastric stomach"—one which always went back on them in times of stress. A good many of these men owed their symptoms to psychological trouble; on investigation they turned out to be cases of gastritis of the real Alexis St. Martin type. In the radiogram they showed nothing but sometimes a layer of residual secretion lying above the contrast meal; the test-meal showed an excess of hydrochloric acid, a high rising acid curve and an associated excess of mucus. Dr Newman wondered whether the clinical picture of a year ago was not utterly different from that seen now. A good deal depends on the diagnosis between duodenal ulcer and duodenitis. The physician should assess the clinical evidence before he considers the radiogram, and should make the diagnosis as a clinician and not as a machine. The majority of cases diagnosed as duodenitis would, if clinical factors were taken into consideration, be called an ulcer. He found no evidence that neurotic factors played an important part in the genesis and maintenance of the ulcers he saw a year ago. Psychological factors are admittedly important in the causation of gastric disorder, but hardly any such factors were operating last winter, and the patients were damaged by their Army diet long before psychological factors could come into play. The distinction between organic and neurotic dyspepsia cannot always be made; many organic cases are neurotic and the ordinary gastric-ulcer case shows a certain mental abnormality. If both factors are present, both should be treated. A certain number of gastric cases in the Army ought to be fully investigated. It is unwise to let difficult cases go in and out of hospital; they are only spreading gastric notions and being useless soldiers. Without proper investigation there is a risk that medical officers are not behaving as physicians at all. There is a tendency to treat a soldier as a peculiar sort of animal. Unless some mechanism for examination exists the gastric case will not always get a fair deal.

Major J. G. SCADDING communicated a paper which was read by Dr J. L. LIVINGSTONE, the hon. secretary. Major Scadding had investigated cases of digestive disorders referred as outpatients by unit medical officers in the autumn of 1940. They contained a preponderance of recent recruits, and in the majority the symptoms had started in civil life. Of a large group with gastro-duodenal symptoms who were examined radiologically, nearly half proved to have peptic ulcers. Some of the patients with proved ulcers had been very young at the first onset of symptoms—the average age was 26. In general the clinical picture of the proved ulcer group corresponded to that usually attributed to peptic ulcer, but some of the histories were far from conforming to the accepted picture. The real difficulty arose in cases where the radiological evidence was equivocal. Temporary dyspepsia might account for a number of the cases not considered clinically to be organic. Many who showed a smooth gastric outline with a normal duodenal cap gave histories highly suggestive of peptic ulcer. The discrepancy between radiological data and conclusions on clinical grounds is one of the most difficult problems of the specialist. The diagnosis of gastritis can perhaps only be established by gastroscopy; the diagnosis of duodenitis seems even less capable of actual proof. The only justifiable diagnosis in these cases is the non-committal one of dyspepsia. Vomiting seems to bear little if any relation to the gastric condition and does not mark any special type of Army dyspepsia. In very few cases in this series were psychological factors regarded as the principal cause of the symptoms. The atmosphere of uncertainty which surrounds dyspeptic cases without radiological examination has a very unfavourable effect. A special unit should be established to deal with doubtful cases.

Sir ARTHUR HURST remarked that in civil outpatients gastric outnumber duodenal ulcers by four to one; in the Army the proportion is reversed, though he could not say why. More than half the gastric cases admitted to the Radcliffe Infirmary during the past year were referred convulsions With these data alone no satisfactory explanation of the time relation of action can be given There is unfortunately not yet any satisfactory test for epanutin in the blood or other body fluids, so that it is impossible to decide whether the shape of the time curve is due to delayed absorption, accumulation or to some slow cellular change Evidently the dosage is even more critical than experience with epileptics would suggest, since the smaller patients show the greater effects, both protective and toxic The dose of three capsules a day seemed to be about optimal, since doubling this dose did not double the effect but did aggravate the toxic signs *The one patient who showed a threshold rise of only* 50% with several toxic signs (case 10) was very emaciated Her impedance angle (Brazier 1933, 1934, Brazier and Grant 1934) was plus 20, well outside the normal range, and suggestive of some degree of hyperthyroidism * It is conceivable that the raised metabolism associated with this condition might have something to do with the patient's apparent idiosyncrasy In using epanutin for the treatment of epilepsy it seems likely that patient trial of small doses is necessary to obtain good fit-control without delayed toxic actions In nearly all the patients discussed here the ataxia and other signs appeared well after the threshold had reached its height

No drug can be properly used until it is fully understood The action of epanutin is by no means clear and its application is therefore largely a matter of trial and error In its effect on electrically induced fits we can see a suggestion of the manner in which it surpasses a sedative such as luminal. Electro-encephalography of essential epileptics shows that, whereas luminal limits to some extent the spread of an abnormal electrical process over the cortex, epanutin actually reduces the size and intensity of the focal trigger mechanism Now in the induction of convulsions by electricity the stimulus consists of a pulse or burst of alternating current Variation of the duration of stimulus actually varies the number of waves or number of stimuli which the brain receives Variation of voltage varies the area of cortex subjected to an effective stimulus When a very low-voltage (say 60 volts) stimulus is used, lasting about 0 5 sec, the type of fit is not as stereotyped in character nor as constant in duration as when a larger briefer stimulus is given Both stimuli may be above threshold, in that a convulsion follows, but the convulsive process is not identical in the two cases When a weak, long stimulus is used the convulsion is often delayed in onset, focal in extent and may last much longer or shorter than the average This is presumably because only a small area of cortex is stimulated effectively, so that the epileptic process does not develop simultaneously in all places, as it does when a strong stimulus is applied and the whole frontal cortex is thrown into synchronous maximal activity The effect of epanutin in doses insufficient to prevent fits altogether is very similar to that of reduction of voltage—the convulsion is more ragged and localised and its length is more variable As a working assumption epanutin may be considered as raising the electrical threshold of the cortical cells so that a stimulus of fixed strength will affect fewer cells But that is not all, the duration of the stimulus must also be increased to compensate for the effect of the drug, which must therefore have some action on the cells which affects their tendency to repetitive discharge In electro-physiological terms this may be attributed to a decrease in the time constant of accommodation of the excitable structure, and it is probably this action which is the more important in fit-control, rather than the simpler threshold raising effect If this is so, it helps to account for the absence of a sedative or hypnotic action, since a moderate increase in accommodation would not necessarily impair the normal functioning of the excitable tissues, although it would decrease their liability to repetitive activity This may be compared with the reverse effect of excitatory drugs, such as tetra-ethyl ammonium iodide (Cowan and Walter 1937) If epanutin increases the accommodation rate in normal brains there is no reason why it should not also have this effect in epileptic brains, and it may well be that the specific anticonvulsant action of the drug is due to this property This theory is speculative, but it accounts for the facts discovered so far, it is hoped to *test the hypothesis by prediction of results in a further* series of observations

SUMMARY

Epanutin in various doses has been administered to ten mental patients undergoing electrical convulsion therapy

In all patients the electrical convulsion threshold was significantly raised In the smaller patients the rise was so great that it became impossible to induce a convulsion at all

The margin between maximum therapeutic and minimum toxic dose is small Six capsules a day had little more effect on the convulsion threshold than three a day, but toxic signs were more prominent

The full effect of the drug may not appear for up to 6 days after the first dose After withdrawal the effect may persist for up to 14 days depending on the frequency of induced convulsions

Even when the convulsions were not entirely inhibited by the drug they were made more variable and ragged, less typically epileptic Partial seizures of the Jacksonian type were more common

Medical Societies

ROYAL SOCIETY OF MEDICINE

AT a meeting of the Section of Medicine on March 25, with SIR MAURICE CASSIDY, the president, in the chair, a discussion on

Dyspepsia in the Forces

was opened by Colonel H LETHEBY TIDY From the time of the first arrival of the British Expeditionary Force in France, he said, attention was focused on the amount of dyspepsia in the Army Of all cases diagnosed on the nominal roll, 50% were said to have some type of dyspepsia He expected to find in his investigations some form of neurosis, or a conventional diagnosis used for convenience in invaliding, but he was surprised to find that almost all the cases had peptic ulcers This great prevalence of dyspepsia and peptic ulcer continued in the military hospitals Nevertheless, gastric disease is not the largest cause of invalidism or of invaliding in the Army The chief causes of dyspepsia are peptic ulcer, including duodenitis and duodenal spasm, a group generally called gastritis but also *known as functional dyspepsia*, and an important group of transient dyspepsias Patients in the last group are not often seen in hospital, but it outnumbers by several times the other two groups together The remaining cases are divided among reflex disorders, malingering (this is extremely rare), and patients who are primarily psychoneurotic During last August the proportion of gastric cases in all military hospitals was 17 3% In recent months the proportion has become lower, and it does not seem to be increasing now that older men are coming into the service Of the organic cases, peptic ulcer accounts for 51 9%, gastritis for

---

* The "impedance angle" is an electrical measurement It might be called an electro histological test of thyroid activity Introduced by Brazier in 1933 it has been adopted by centres in many countries as a substitute for or supplement to measurements of basal metabolic rate The whole body of the patient is made an arm in a modified Wheatstone bridge and measurements are made with a very small alternating current at about 10,000 cycles per sec At this frequency the body behaves not merely as a simple resistance but also as an electrical condenser The impedance angle is a gauge of the magnitude of this condenser attribute It is not a "skin effect" but is a characteristic of the body cells as a whole It is not affected by exercise or drugs, except thyroid extract or thyroxin It has been found a very trustworthy test of thyroid activity, being probably a measure of the average electrical thickness of the cell membranes Brazier devised an arbitrary scale, corresponding with the clinical B M R scale A reading of plus 20 is therefore above the normal range for women

ZINC OXIDE STRAPPINGS
OF RELIABLE QUALITY

The surgical adhesive plaster products of Herts Pharmaceuticals Ltd. are guaranteed to be good and serviceable for two years from the date of manufacture

LEUKOPLAST

—THE ORIGINAL ZINC OXIDE PLASTER

Prompt and firm adhesion without warming
Non-irritant to normal skins
High tensile strength and pliability

LEUKOPLAST ELASTIC

—ZINC OXIDE ELASTIC PLASTER

Non-irritant
High degree of elasticity
No unspread edge or untidy fringe

Wound with the adhesive inside. Short lengths may be cut off, e g., for fixing dressings without leaving an exposed sticky surface on the roll

⁂

HERTS PHARMACEUTICALS LTD., WELWYN GARDEN CITY

for hæmorrhage, but Colonel Tidy said that this and perforation were extremely rare in the Army The radiologists may be misleading the profession to some extent, and the clinician believes too much in radiological reports Many soldiers may be diagnosed on radiological grounds as duodenal ulcer because of a healed crater He supposed that if a gastric patient is doing important work and the Army wishes to keep him, it will be considered worth while to give him strict treatment and to return him to duty subject to definite instructions for aftercare He wished some arrangement could be made between Army and civilian hospitals for the continuation of treatment All the men invalided for gastric trouble should return as soon as possible to civil employment, he hoped they were receiving strict treatment during the weeks before they were boarded

Lieut -Colonel S J **Hartfall** said he was distressed to hear that the Army did not propose to provide specialists with gastroscopes Gastritis can be diagnosed gastroscopically, and the instrument also enables a large proportion of definitely negative reports to be given He could not understand how Newman and Payne found so few neurotics, the incidence of a neurotic basis among his dyspeptics was about 60%—patients who were entirely negative to gastroscopic examination and could be handed over to the psychiatrist Some 20% had a superficial patchy gastritis which he treated by keeping them in bed for ten days to a fortnight and washing out the stomach every morning with hydrogen peroxide a drachm to a pint, followed by 2 drachms of one of the aluminium hydroxide preparations, and a teaspoonful of the same drug every four hours between meals, which should be light Unsuspected chronic gastritis is not likely to be the explanation of many cases of dyspepsia which give negative findings on examination

Mr **Reginald Payne** admitted that the picture of the dyspepsia which he and Newman saw was largely different from the present one He found considerable dislike of gastro-duodenal patients and a tendency to regard them too easily as malingerers He thought that this discussion had demonstrated the need for an absolutely accurate diagnosis whenever possible An adequate history cannot be stated in two or three lines It is important that one person should summarise all the evidence and that the diagnosis should not be left to the radiologist or to anyone who has not all the evidence before him Very few of the cases he investigated with Newman should have been accepted for the Army

Colonel E B **Marsh** said he was that rare person, a regular Army physician who had been practising medicine in the Army all over the world since the beginning of the last war Only one question has to be answered in dealing with a dyspeptic soldier is he fit to be a soldier, and if so, in what category ? To lose sight of this aspect is to waste much time The incidence of ulcer is greatest between 19 and 22 in the Army instead of between 30 and 35 in civil life, because cases are reported earlier He and his regular colleagues do not use the term gastritis except as a precise description He has been accustomed to divide these patients into bun-eaters and beer drinkers He does not recognise the term " soldier's stomach " The gastroscope cannot be obtained anywhere, and to try to produce it specially seems unnecessary Clinical evidence should be sufficient to decide whether or not a man is fit for duty

Reviews of Books

The Art of Surgery

A Textbook for Students and Practitioners (4th ed) By H S **Souttar**, D M , M Ch Oxfd, F R C S London William Heinemann Pp 779 2 vols 25*s*

Mr Souttar explains that his object in changing the format of his textbook has been to encourage its use as a companion for the student, rather than as an unwieldy book of reference This change is welcome, for the popularity of the work with students is due in the first place to the fresh and interesting way in which the various subjects are presented, carrying the attention on from paragraph to paragraph The thumb-nail illustrations have increased in number since the last edition, and are an excellent method of focusing attention The author has had in the forefront of his mind the importance of developing in students a sense of proportion, he avoids dwelling on the details of surgical operations and allows himself to linger longer where he is dealing with fundamental principles ' The section on fractures is the weakest, containing passages that will confuse, and may even mislead, the student brought up in the modern regime of exact and prolonged control of fractures by splinting—for example, the recommendation that in treating fractures of the arm or below the knee the splints used should be in almost all cases removable, so that the limb can be daily exposed for inspection and massage However, Mr Souttar quotes the Winnett Orr method of closed plaster treatment of compound fractures, where the splint is certainly not removed daily Fracture of the neck of the femur, on the other hand, is described without reference to any method by which union can be obtained—he mentions neither the Smith-Petersen pin nor the Whitman plaster Other omissions are probably more deliberate, serving an educational purpose such as the lack of any reference to the delayed treatment of acute appendicitis The clinical descriptions are a pleasure to read, and the classification and arrangement clear and explanatory

Experimental Physiology

(2nd ed) By **George** H **Bell**, M B Glasg Glasgow John Smith and Son Pp 192 6*s*

This book has been enlarged and the arrangement altered to a systematic one in place of the programme based on the Glasgow courses of experiments It is still scarcely comprehensive enough to constitute a standard practical textbook, and is likely to be more use to Glasgow students than to others, but the experiments have been carefully selected so as to be representative and most of them are clearly explained The book is certainly good value for the money

Weight Reduction Diet and Dishes

With tables and recipes suitable for diabetics (2nd ed) By E E **Claxton**, M B Lond London William Heinemann Pp 201 8*s* 6*d*

War conditions have altered our outlook on weight reduction—it may even be, as it was in the last war, that we shall undergo compulsory slimming, though we hope not There certainly has been and will be a qualitative change in the nature of the foods we can obtain This book will be of use to those who want a brief dogmatic statement of how to obtain the vitamins which changes in the foods available may remove from our diet though the Ministry of Food has already knocked one of the recommendations on the head It is that one pint of milk, a liberal helping of green vegetables and an orange should be used to satisfy the daily requirements of vitamins and inorganic elements Today watercress, mustard and cress, radishes, and raw cabbage or turnip salad must take the place of the orange It is a pity that Miss Lucy Burdekin in her interesting recipes has included none for raw, vitamin-C-containing vegetable salads

This book will find a new and useful place in supplying the ordinary housewife with recipes for dishes made with little fat and no sugar She is naturally chary of replacing sugar with saccharin for she does not know the proportions Here she will find recipes for such things as sugarless marmalade and sugarless jams, and throughout the recipes the quantities of saccharin and a butter substitute (Lister's Golden Spread) are given Moreover there are recipes for pickles, chutneys and sauces with little or no calorie value which would be useful in " getting down " the diets to which we may have to accustom ourselves This edition has not lost any of its original value to doctor and patient by becoming more useful to the ordinary housewife Dr Claxton is firm on the point that any weight reduction by whatever means should be done under the guidance of a doctor, and he does not advise people to think of reduction unless they are 15–20% above the average weight Slimming for slimming's sake is a mistake, but if anyone for his health's sake has to slim this is the book to tell him how to do it

THE LANCET

LONDON SATURDAY APRIL 5, 1941

GETTING A MOVE ON

It was one of the lessons of the last war, confirmed in this, that the life of a seriously wounded man often depends on how soon he reaches the hands of the surgeon Delay may mean that sepsis and more particularly gas gangrene gain a footing from which no subsequent treatment can dislodge them In the case of air raid casualties time may be lost at the incident, during the journey to hospital, and at the hospital itself, and the likelihood of delay is not reduced by the division of authority which still exists The teams which gather the wounded from the street, care for them throughout their treatment and return them to their homes should be made up of colleagues owning but one master Moreover, it was not at first realised that the successful treatment of casualties is the business of the whole of the A R P services, and not least of the fire brigades, police and wardens Nor was it appreciated that though an admirable system of central and sub-control posts and report centres had been designed and brought into being success would often be thwarted by failure of coordination at the site of a major incident For reasons of finance some of the services were established without non commissioned or commissioned officers, and without these, even after long and rigorous acquisition of discipline, troops may fail in a crisis The "incident officer," when he exists and when he is of the right stuff, is invaluable he quickly brings order from disorder, he directs priority of services, he parks his vehicles so that none embarrasses the action of another, he keeps his area free for manœuvre, he acts upon and implements the advice of his specialist officers—police, fire, engineer and medical The "incident doctor," now recognised as an indispensable entity, can inspire the activities of his first aid parties and ambulances, and of those members of rescue and other services who find themselves actually tending the wounded, but "command" must leave him an unimpeded field for his own work His presence gives confidence, his experience is a stand-by, most appreciated by the most competent of his party leaders, his syringe is at hand where needed, he is there for appeal when the difficult case leaves first aid men in doubt He knows when a single case demands the immediate dispatch of an ambulance, he knows when a casualty can safely wait for the full complement of stretcher-cases to fill the vehicle

With the incident officer and the incident doctor functioning as they should, it is certain that a wounded man will start his journey to hospital at the earliest moment feasible It will not be at the site of bombing that time will be lost, and the time saved must not be wasted in hospital There is nothing to be gained by rushing at the operative task None but minor injuries are ready for immediate operation, and even the more lightly wounded are often so begrimed that, apart from the need for warmth and rest, time must elapse before they are ready for the theatre But delay at this stage should be intentional—when the patient is ready for the theatre the theatre should be ready for him This means that no hospital should be sent, or should accept if sent, more patients than it can cope with efficiently within a given number of hours Some 10–12 cases for each operating-theatre seems to be the limit A sure means must be found for intimating to those who direct the ambulances that a given hospital has taken in as many casualties as it can deal with As a peripatetic correspondent urges, hospitals must not let pride in their competence and willingness for a long spell of work affect their estimate of what each link in the chain of their organisation can stand When the breaking point looks like being reached it should be the routine to notify the central control of A R P services, so that other casualties are diverted to other and less busy hospitals, and there should be no false shame in calling for the help of visiting teams in good time so that when they come exhaustion will not cloud their welcome

EPIDEMIOLOGY OF YELLOW FEVER

For three centuries at least yellow fever has periodically ravaged the larger seaboard towns and cities of West Africa and tropical and subtropical America Whether the disease was originally one of West Africa, and was conveyed thence by ships to the West Indies and to South America, or whether it has flourished in South America from remote times, is doubtful From the African and American endemic areas it is known to have been transferred to Mexico, the United States, the Canary Islands, Spain and Portugal, Italy, and the small islands of Ascension and St Helena in the South Atlantic In 1865 an outbreak even occurred in Swansea, but the disease, so far as is known, has never invaded Asia or Australasia, although it was feared that the opening of the Panama Canal might facilitate the invasion, and more recently the development of rapid air transport has occasioned alarm as a potential method of spread

An American commission in Cuba at the beginning of the present century established that a mosquito, *Aedes ægypti* (*Stegomyia fasciata*), served as an intermediate host for yellow fever, and that this mosquito, feeding on a patient during the first three days of his illness, could, after a lapse of about twelve days, transfer the infection by its bite to non-immune people *Aedes ægypti* is essentially a domestic, or house-haunting, species of mosquito and is of world-wide distribution The commission demonstrated that mosquito transfer was the normal method by which the disease spread from one individual to another and showed that contact infection did not occur in nature They therefore postulated that the disease could be effectually controlled by measures directed towards the destruction of mosquitoes and the protection of the sick against the bites of these insects Two theories—that yellow fever was primarily a disease of the large maritime towns, and that it was in nature conveyed from man to man solely by *Aedes ægypti*—determined the policy of the Rockefeller Foundation in combating the disease in South America A vast amount of labour and large sums of money were expended on destroying what were believed to be the "seed-beds of infection," in the belief that these seed-beds were few in number and that their sterilisation would result in the disappearance of the disease not from them alone but also from the tributary areas periodically reinfected from them The improved sanitation of Panama and Havana

BYNIN AMARA

In Convalescence from Influenza the characteristically profound lassitude and the low blood-pressure are likely to be accompanied by diminution of the capacity for digesting food and by slight anæmia For the speedily effective treatment of these disturbances BYNIN AMARA is most useful It contains quinine phosphate, iron phosphate, and alkaloids of nux vomica, in Bynin Liquid Malt

In bottles at 2/-, 3/6, 6/6, and 12/- (plus Purchase Tax)

extending from the West coast to the Anglo-Egyptian Sudan, Uganda and Abyssinia in the east, and from the Sahara in the north to Angola and the Belgian Congo in the south -Over large tracts of country in which positive mouse-protection tests were obtained no clinically recognised yellow fever had ever been recorded Silent endemic areas were demonstrated in Africa just as in South America The extension of the test to domestic animals (cattle, sheep, camels, horses and monkeys) has revealed that certain individuals possess immunity to the virus, though it is known that the African monkeys in the endemic areas do not show any clinical manifestations when artificially infected with it A disturbing feature has been the rapid rise in the number of immune persons in certain districts In a district of the southern Sudan the proportion of natives whose blood gave positive protection tests rose from 0 to 18% within four years, without any clinically recognised yellow fever In this district *Aedes ægypti* is almost non-existent It has not yet been established that jungle yellow fever exists in Africa, but these facts suggest that it does The potential danger of the situation is obvious, and is illustrated by a serious epidemic in the Nuba Mountain district of Kordofan Province of the Anglo-Egyptian Sudan This epidemic, the greatest so far recorded in any part of Africa, occurred in a district where up to October, 1940, no case of the disease had ever been recognised clinically, although a mouse-protection-test survey conducted there some years before had shown the presence of the infection The outbreak involved an area of 6000 square miles, there were 1600 deaths among the 15,000 recognised cases, and it lasted a couple of months before being brought under control In so far as risk to an immigrant European population is concerned, the solution is easy The artificial production of immunity with attenuated strains of virus is both effective and simple , and the protection afforded is of considerable duration To deal with the indigenous population is a very different matter, as it is obviously impracticable to immunise them all The most that can be done is to deal with outbreaks as they arise and above all to forestall the advent of the disease in the towns, particularly those on the East coast of Africa, by efficient sanitation and mosquito control This is already being seen to

MILITARY STOMACH TROUBLE

THE main facts about dyspepsia in the Army are becoming clearer as the number of published reports increases The problem presents itself very differently to the various types of medical officer in the Army, and each of these has his own difficulties The variety of clinical approach was illustrated in the discussion at the Royal Society of Medicine reported on another page The unselected cases come first to the regimental M O , he finds among the total sick a large number of dyspeptics, and he has to decide which cases to refer to the medical specialist, and which to treat himself in the unit We badly need reports from representative regimental M O s on the material which they see , no single report would be final, because the nature of the M O determines, to some extent, the number and nature of the patients he sees An over-strict M O will find that his patients tend to be few and seriously ill, a new M O will see a good many who are “ [illegible] ” a slack or over-conscientious one will find himself flooded with trivial complaints. But in order to get a notion of what dyspepsia in the Army means it is essential to find out how it presents itself in the first instance It would probably be difficult to compare these findings with what was ultimately discovered about the patients, unless the survey was completed by a medical specialist, who could complete the record with the subsequent hospital findings

The problem as it appears to a medical specialist is again not the same as it appears in hospital , the type of case found in the wards depends on what he selects for admission Moreover, he determines to some extent the nature of the material he sees If he admits too many trivial cases the regimental M O feels justified in sending more of the same sort, and if he is known to be interested in some specialty cases of this type will tend to predominate Most of the information available is derived, naturally, from hospital material because cases there are most completely investigated and seem to be most worth publishing There is an opportunity here for the medical specialist to arrange with regimental M O s to keep records and publish with him a combined survey giving a complete picture of the cases This would reduce to their true proportions estimates of the incidence of the different types of dyspepsia with which the Army is troubled

The doctor in charge of the patients in hospital is well advised to have his dyspeptic patients examined as thoroughly as possible , his difficulty is the balancing of all the information in the light of the case-history in order to arrive at a diagnosis Once the diagnosis is settled, treatment and disposal are not so difficult, although they present their own special problems The difficulty is to deal properly with an inadequately diagnosed case In weighing up the evidence it is important not to allow any one item more than its due importance , X rays present a special difficulty If an ulcer crater is visible is it an active ulcer or a scar ? And still more, is a duodenal distortion an active ulcer or a scar ? And if no crater is visible but all the other evidence points to the diagnosis of ulceration, how is the medical board to be convinced, tending as it so often does, to require ocular demonstration ? There are, and it is right that there should be, differences between different radiologists in their attitudes towards the interpretation of results , the only uniformity to be desired is uniform accuracy But a responsibility rests on the radiologist, because he, and he alone, has had the advantage of seeing the screening He is the first to gibe at the clinician who insists on interpreting the radiograms for himself The value of real cooperation between radiologists and clinicians is illustrated by SAFFLEY S [1] recent paper in which he compares the radiological with the clinical findings in over 300 dyspeptic soldiers Ulcers were demonstrated radiologically in about 40%, which corresponds with the general run of figures since the heavily ulcerated population of reservists investigated by PAYNE and NEWMAN was discharged from the Army Only 2 2% were diagnosed radiologically as ‘ duodenitis ” Half the patients examined showed no radiological abnormality, and although these include three ‘ normal ” gastro-enterostomies and a few other hardly normal appearances the figure suggests that many unnecessary cases were being admitted for investigation resulted in the disappearance of the disease from these two cities, and also from many other cities of the Gulf of Mexico and the Caribbean Sea, the clearing of Santos, Rio de Janeiro and Nichtheroy was followed by the apparent disappearance of yellow fever from the whole of South Brazil, while anti-mosquito campaigns in the principal ports of the Amazon Valley led to its elimination from this vast region After a campaign in Guayaquil, and another in Northern Peru in 1920, no further cases were recorded on the Pacific coast of South America Similar results were later obtained in Colombia, Mexico and Central America, and during 1925 only three cases were reported from all the Americas, the complete eradication of the disease from America appeared to be in sight In 1926, however, the movement of non-immune troops through north-east Brazil was attended by the temporary reappearance of the disease in several states In 1928, yellow fever again broke out in Pernambuco and Sergipe, and shortly afterwards it appeared, after a lapse of twenty years, in Rio de Janeiro The fact that Rio was about a thousand miles from the nearest point known to be infected during the preceding year did not escape notice, and the origin of the outbreak was not determined During the height of this latter outbreak cases were recognised, attributable to it, at various points over a 4000 mile stretch of coast, from Buenos Aires to Belém, at Para and up the Amazon river. The theory that the destruction of the large seed-beds of infection alone would suffice to eliminate the disease had, therefore, to be abandoned, and steps were taken to include smaller towns and rural villages in the campaign Thus "rural" yellow fever was recognised as a factor in epidemiology in addition to the "urban" type

[1] Saffley, R. *Brit J Radiol* 1941, **14** 96

Within the next few years the introduction of two methods of diagnosis profoundly altered the previous conception of the epidemiology of yellow fever These were viscerotomy and the mouse-protection test The first depended on the fact that certain specific changes occur in the livers of people dying of yellow fever An instrument, the viscerotome, was devised to obtain samples of liver from cadavers without the necessity of performing an autopsy This instrument could be used by laymen, and its employment was insisted on in certain areas whenever a person died within 11 days of the onset of a febrile condition, whatever the clinical diagnosis The viscerotomy services examined specimens from many thousand bodies over considerable areas of South America, and demonstrated that many people were dying of yellow fever in the absence of "visible" outbreaks of the disease They also showed that the distribution of the disease in "silent" endemic areas was much more extensive than had been expected, and further that yellow fever caused a considerable mortality among children, thus dispelling the idea that the disease was a mild one when it attacked children in endemic areas The mouse-protection test, devised about the same time as viscerotomy, depends on the fact that the serum of people who have recovered from yellow fever contains specific immune bodies If such serum is injected into a mouse at or about the time that the mouse is infected intracerebrally with a neurotropic strain of yellow fever virus, normally lethal to it, the mouse is protected against the effects of the virus The test, therefore, shows if an individual has previously had yellow fever (or has been artificially immunised against it) The application of the test in South America again demonstrated that the disease was far more widespread than had been thought, and that it was occurring in areas where it had not previously been clinically recognised A further use of the mouse-protection test is in dating the time of the occurrence of the disease For example, if no children under six years give positive tests it can be assumed that the disease has not been present in that district for the last six years The test also established the fact that yellow fever was occurring in the complete absence of the accepted vector, *Aedes ægypti* The aedes-free endemic areas were chiefly jungle districts, and the disease was found among workers in the forests, this was an entirely unsuspected aspect in the epidemiology of yellow fever It has now been established that in South America today yellow fever is primarily a jungle infection which *Aedes ægypti* is not the vector, and that man not an important reservoir of the virus What tl most important reservoir is has not yet been finall established, but it has been observed that tl American howler and other monkeys die considerable numbers at times when human infectio are occurring in the forests Three species American jungle mosquitoes, naturally infected wi the virus, have been captured

The present position in South America is that the are three types of yellow fever—the *ægypti* tran mitted urban and rural types, and the non *ægypt* transmitted jungle type The first two are acqure indoors, are likely to involve non-immune people all ages in the vicinity, and tend to spread along th routes of human travel They are dependent fo their maintenance on the close association of man an *Aedes ægypti* The third, or jungle, type is onl acqured by forest workers, does not spread to othe members of the community in the absence of *Aede ægypti*, and spreads through jungle irrespective routes of human travel The first two are relativel readily controlled by anti-*ægypti* measures, but th last, which now dominates the epidemiological pictur in South America, can apparently only be brough under control by individual immunisation of th exposed members of the population In the laboratory the jungle virus is readily transmissible by *Aede ægypti*, and thus if this virus is introduced to a *ægypti* district it can give rise to the epidemic *ægypti* borne form of the disease, conversely, the *ægypti*-born virus can be conveyed by the appropriate forest mosquitoes Clinically, pathologically and immunologicall the various types of the disease are indistinguishable

In Africa the position much resembled that in Sout America Yellow fever ravaged the maritime citie of West Africa, and, in view of the American work attempts were made to clear up those foci of infectio where *Aedes ægypti* was present in large numbers Freetown, Lagos, Port Harcourt, Calabar and othe cities were efficiently sanitated, and the severe urba and rural epidemics of the disease were controlled but the sanitary work done in these cities did no prevent outbreaks in Mamfe, Kano and other remot places The mouse-protection test was employe extensively in Africa, with the result that immun people of all ages were found over a large area abstinence, is not high, Ryle, indeed, regards it as very low. Probably susceptibility to tobacco sufficient to produce dyspepsia in an otherwise normal stomach is exceptional, most people being immune, though tolerance may diminish with advancing years or after an illness. There is some reason to regard intolerance as limited to those with the ulcer diathesis but this is a complex subject, and in spite of the amount of work done on it would still repay investigation. We do not yet know, for instance, whether the gastric symptoms produced by tobacco, which may closely simulate peptic ulceration, are primarily due to pyloric spasm, as might be supposed from the vigorous peristalsis and diarrhœa sometimes seen in young smokers, or to hyperchlorhydria which excites pyloric spasm. Nicotine acts on the synapses of both the sympathetic and the parasympathetic systems first as an excitant and later as a depressant. The results of a dose will depend on the balance between sympathetic and parasympathetic effects. The parasympatheticotonic person, who normally has a free flow of gastric juice, an active gut and relaxed sphincters will presumably begin by showing an increase in these characteristics, followed by spasm of the sphincters and inhibition of bowel movements; the reverse picture will be seen in the sympatheticotonic person. Irregular action between the two systems, however, might presumably produce any combination of symptoms including the pyloric spasm, active gastric motility and hyperacidity of the dyspeptic. Various other poisonous constituents of tobacco have been blamed for its ill effects—carbon monoxide, pyridine, ammonia, collidine, pectin, and even prussic acid and arsenic—but it is hard to ignore an observation made some years ago by Henry Moll[10] of Leeds. He was giving gr 1/10–1/5 of nicotine thrice daily hypodermically to cases of post-encephalitic parkinsonism in an attempt to reduce spasticity, and in 6 cases fractional test-meals were done before and after a 2–3 weeks' course of this treatment. Of these, 1 showed no change in gastric acidity, but in the other 5 there was a definite rise; in 1 patient, indeed, whose acidity had been normal before treatment there was a gross hyperacidity after 10 days on nicotine gr 1/5 three times a day. This fits in with the clinical experience that there is a wide variation in the response of the individual stomach to smoking.

HOURS OF WORK IN GERMANY

WHEN the National Socialist government came into power normal working hours in Germany were fixed at 8 in the day and 48 in the week and could be altered only by agreement between the employers and workers' organisations. With the suppression of the latter the government became the sole authority, and, by means of the regulations it introduced, a 10 hour day gradually replaced the 8 hour. By 1936, according to Waelbroeck and Bessling,[11] the 10 hour day had become usual in the metal-working building and similar industries, and the practice extended in turn to most of the industries working for rearmament. Similarly, early in 1939 the length of the shift for miners was extended by 45 minutes to 8¾ hours. With the outbreak of war all restrictions on normal hours of work for adult men were abolished, as were the increased rates of pay for overtime and night work and for work on Sundays and holidays. Holidays, in fact, whether paid or not, were to be done away with. How far the authorities made use of their wide powers is not known but it is significant that less than 3 months after the outbreak of war it was found necessary to restore the regulations at least partially. "He who wishes to work for the reconstruction of the Reich," Marshal Goering had said in 1938, "must not only work 8 hours a day but must work as he has never done before." But the disadvantages of excessive hours of work were pointed out as early as the beginning of 1939 and by the end of that year the government restored a limit to the working of overtime in excess of the normal 8-hour day (10 hours being the general rule) and reintroduced annual holidays. The reason given for the reversal is that the care of the worker's health must be a fundamental object of labour protection even in war-time, and that the relaxation of regulations was justified only in an initial period. It seems likely, Waelbroeck and Bessling conclude, that the use made of the facilities for extending hours of work was excessive. Germany too has probably re-learnt the lessons of the last war only by practical experience.

INDUCTION OF LABOUR WITH UROSELECTAN B

WHEN amniography was first employed to obtain a radiogram of the placental situation in suspected cases of placenta prævia, various substances were used to render the amniotic fluid radiopaque. Among these was Uroselectan B and the operators who employed it were quick to notice that a high proportion of their cases went into labour soon after its intra-uterine injection. Playfair[1] has now used the drug as a deliberate method of inducing labour.

Uroselectan B is an iodine compound of complex nature combined with an organic base so that in theory the iodine is not free to exert toxic effects on the body tissues, and this contention appears to hold good so far as intra-uterine introduction is concerned since it has been used for many years in cases of suspected placenta prævia without any harm to the mothers having been reported. Serial radiograms of the uterus after the introduction of uroselectan demonstrate that its maximum concentration lasts about half an hour, and no shadow of the amniotic cavity is to be seen after thirty-six hours; Burke[2] has been able to show that half of the drug is recoverable from the maternal urine at the end of this time. The fœtus in many cases shows a well-defined shadow of the stomach and colon, proving that it drinks its own amniotic fluid in sufficient quantities to render its alimentary tract radiopaque. The exact method of action of uroselectan remains obscure; it is more likely to be a local than a general one, since labour has not been observed to be prematurely induced by this drug in cases in which it was used for intravenous pyelography. Another reason for supposing the action to be local is that hypertonic saline and hypertonic glucose solutions when injected into the amniotic cavity will induce labour with a fair degree of certainty, the solutions employed being 10 c cm of 30% saline or 50% glucose.

Playfair found the optimum dose of uroselectan to be 10 c cm (half the one recommended for amniography), though he originally employed double this dose. After emptying the bladder, if necessary by a catheter, a point is chosen midway between the symphysis and the umbilicus; this point must be carefully palpated to exclude the interposition of maternal gut between the abdominal parietes and the uterus, and the exact fœtal position should be defined. Any operation scar in this region is a contra-indication to the use of uroselectan, for it increases the likelihood of maternal gut having become adherent, and though the risk of puncturing the intestine is probably exaggerated it is not one to be needlessly invited. Local anæsthesia and a fine lumbar-puncture needle are used. No uroselectan must be injected unless liquor amnii dribbles readily from the needle after removal of the stilette. Before and immediately after the injection it is important to count the fœtal heart-rate. If the placenta is inadvertently encountered it has been found to be safe to traverse this with the needle. Playfair advises that the best and quickest results are to be expected if the patient is kept up and about

Annotations

LEUCOPENIA

LEUCOPENIA was always a useful diagnostic pointer, but recent advances in chemotherapy have brought it into prominence as an indication that the dose of a sulphonamide is approaching the limits of safety Lawrence[1] urges physicians to "put more thought to leucopenia" and points out five possible mechanisms for its production diminished manufacture of cells, increased elimination, increased destruction, redistribution in the vascular channels, and redistribution in the body as a whole When we speak of leucopenia we nearly always imply a lack of polymorphonuclear leucocytes (lymphopenia is only of importance in the control of radium treatment) and Lawrence deals mostly with granulopenia Diminished manufacture of granulocytes has received most attention since examples of it are now well known, it occurs as part of a general disturbance of blood forming tissue in classical aplastic anæmia and probably also in pernicious anæmia and splenic anæmia Acute agranulocytosis, which is apparently a primary disease of the granulocyte forming tissue, has been extensively studied and the disappearance of the granulocytes has been traced to failure of the myeloblasts (the stem cells) or the myelocytes (the intermediate stage) to mature into adult cells The actual marrow picture varies according to the stage of the disease but at times myeloblasts may be the only representatives of the granulocyte series The cause of this arrest of maturation is most often a drug to which the patient is unusually sensitive, amidopyrin and the sulphonamides being the chief offenders Plum[2] was actually able to demonstrate in a patient the disappearance of myelocytes from the bone marrow after a dose of amidopyrin But this is not the whole story, in some cases, after prolonged administration of a drug, especially one of the sulphonamides, agranulocytosis appears fairly quickly If myelocyte formation ceases development of agranulocytosis must, of course, be rapid, since the life of the polymorphonuclear leucocyte is only about 2–4 days, and R L Haden has estimated that some 5–10 billion new cells are required every day But Plum and others have shown that in some patients only a few minutes elapse between giving a small dose of amidopyrin and the disappearance of granulocytes from the blood, and Vejlens[3] found that certain hydrophile colloids like globulin, which produce a leucopenia when injected intravenously, do so by causing the white cells to take up a marginal position in the venules of internal organs such as the liver, spleen, and omentum, they cause a sort of "leucocytic shock," since such leucocytes are temporarily out of the circulation This seems a possible explanation of the sudden disappearance of circulating granulocytes in sensitive patients, and fits in with Israels and Wilkinson's[4] observations that after a single test-dose infection can call back some of the granulocytes into the blood and that the rate of recovery seems uninfluenced by pentnucleotide Lawrence and his co workers have found this mechanism at work in the omental vessels of cats which had been given the virus of an infectious agranulocytosis—a disease which also arrests maturation of the granulocytes in the bone marrow This combination closely resembles that found in human agranulocytosis, and the mechanisms may be the same There is no evidence, however, that virus infection is responsible for even those few cases of the human disease not traceable to drugs Another condition which probably falls in the "diminished manufacture" group is the chronic neutropenia of which Piney[5] has reminded us As originally described it presented a distinctive clinical syndrome of apparently causeless fatigue and lassitude, the only pathological finding was a granulopenia of less than 200 cells per c mm The disease is rare, but all who have reported cases agree on the usual failure of treatment, including pentnucleotide, to influence the leucopenia, Piney's case recovered after receiving Hepatex T, a fact for which he can offer no explanation When referring to redistribution of granulocytes in the body Lawrence has in mind the paradox seen best in some cases of acute leukæmia, when the tissues are packed with leucocytes but the blood contains fewer than normal Robertson and Yu[6] have suggested that redistribution in the internal organs is the cause of the leucopenia of typhoid fever, since they were able to produce this effect with toxic filtrates of *Bacterium typhosum*, the missing leucocytes were found in the vessels of the lungs, spleen, and other organs Convincing clinical examples of increased destruction or increased elimination of leucocytes have yet to be produced, such events are not easy to demonstrate The researches quoted warn us that toxic inhibition of leucocytes may be brought about in a variety of ways among which redistribution is important

SMOKER'S DYSPEPSIA

THERE are still differences of opinion about how far smoking interferes with gastric digestion, your moderate smoker will maintain that his cigarette after meals helps by putting him in the right frame of mind for efficient digestion, but at the other extreme there is a lot of evidence that smoking raises gastric acidity and so both increases the chances of duodenal ulceration and delays the healing of established ulcers[7] This is to some extent a war-time problem, for smoking becomes more popular under war conditions, especially among those who serve by standing and waiting, and Beattie[8] has lately gone so far as to suggest that the kind friend who sent a million cigarettes to the troops in France might have done their gastric mucosa more good by sending a million glucose sweets or malted milk tablets instead Ehrenfeld and Sturtevant[9] have reviewed current opinions and carried out test meals on 33 normal people and 23 patients with peptic ulceration, on the first day the subjects took their meals without smokes, and next day after two cigarettes We are not told whether they were smokers or not, neither are we given any particulars about the type of ulceration in the ulcer group, and th smoking was always done before the meal Moreover for some reason the picture was complicated by givin each subject 200 c cm of 7% alcohol (the equivalent of glass of old ale) as soon as the fasting juice had bee removed The results therefore compare the gastri acidity after an alcoholic drink with those after a alcoholic drink plus two cigarettes It was found tha in 25 of the 33 normal people (76%) and 20 of the 2 ulcer patients (87%) smoking raised the gastric acidity In 10 subjects (presumably ulcer patients) analyses wer done on three successive mornings—first without smoking next after smoking two ordinary cigarettes, and last afte smoking two partially denicotinised cigarettes In 9 o these 10 there was a definite rise in acid values afte ordinary cigarettes, whereas after the denicotinised one 5 showed *no change and* 5 only a slight increase i acidity This suggested, though by no means proved that it was the nicotine rather than other substances i the tobacco which was responsible

The incidence of dyspeptic symptoms directly due t smoking, as shown by their disappearance after complete

Special Articles

U S A VERSUS A M A

THE great trial in which the American Medical Association has to defend its attitude towards certain methods of "group medical practice" is shown to be well under way by an instalment (just received) of the verbatim report which the association is publishing in its journal[1] Two counsel have made opening statements for the prosecution The first has explained how the Home Owners Loan Corporation initiated the project of Group Health Association Inc , because H O L C (if we may adopt the convenient use of initials so well developed in America) found that its borrowers needed so many loans to meet doctors' bills, and thought that an ampler and better medical service preventive as well as curative, could be furnished cooperatively through G H A The defendants include not only the A M A but also the Medical Society of the District of Columbia the Harris County Medical Society, the Washington Academy of Surgeons and 21 named individuals Counsel alleged a conspiracy to prevent the 800 or more doctors of the Medical Society of the District of Columbia from accepting employment with G H A , to obstruct G H A in its efforts to obtain doctors from practitioners who were not members of the society, to attack doctors who joined G H A and to persuade them to abandon the connexion under threat of professional discredit in their practices and in their hospital work, and lastly to induce all local private hospitals to join in the boycott of G H A by refusing to admit Group Health doctors to hospital privileges A subcommittee of the A M A , it was said had reported that G H A was unethical and that participation in it by any member of the District of Columbia Medical Society would make him liable to disciplinary action as well as deprive him of courtesy facilities at various hospitals which the A M A had coerced into the boycott

The additional opening statement by a second counsel for the prosecution was mainly concerned with what, without any intended disrespect, might be called blue-book material He outlined the general developments of preventive medicine, bacteriology radium, cardiography and X-ray examination and dealt with the report of the American expert Committee on the Cost of Medical Care His object was to show that families in the lower income-groups receive too little medical service and find the cost of illness disastrous This information was material to indicate that Group Health Association and similar organisations improved the distribution of medical care and spread the cost by a system of periodical payments The American College of Surgeons, said counsel, had recommended in 1934 the continuance of experiments with periodic prepayment plans because they gave hope of more adequate medical care for the low-income groups A week later the A M A had passed a resolution condemning the college for its recommendations The A M A insisted that any such plan should comply with its own general principles One of these was that the plan should embrace all the qualified physicians within the locality , another required the cost of medical service in any plan to be borne by the patient who could afford to pay at the time when it was rendered The A M A , alleged counsel was hostile to group practice on the prepayment basis and had gone beyond peaceful persuasion in its methods

It may be convenient at this point to note that these proceedings are criminal, not civil There is an indictment, running into 30 pages, alleging conspiracy and violation of the so-called Sherman Anti-Trust Law This statute, named after its sponsor John Sherman (the younger brother of the famous general of the Civil War), was passed in 1890 and has since been modified Not content to rely on the common-law doctrine which makes agreements ' in restraint of trade " unenforceable, it prohibits under heavy penalties any contract, combination or conspiracy which restrains trade or attempts to establish monopoly In England we should expect a case of this nature to be dealt with not by a criminal prosecution but by an application to a Chancery judge for an injunction and a declaration of the rights of the parties Our classic authorities on the law of restraint of trade are mostly decisions in civil proceedings—the Mogul Steamship case in 1892, the Maxim-Nordenfeldt case in 1893, and the pronouncement by Mr Justice Astbury in the Firemen's Union case in 1926 which exercised no small influence upon the general strike It is perhaps unnecessary to explain that the District of Columbia is (like Canberra in Australia) a federal area lying outside the jurisdiction of the separate states It was carved out of Maryland on the north and Virginia on the south and it accommodates the federal government of the whole country There are in America many towns called Washington , this one is distinguished as "Washington, D C"—Washington in the District of Columbia Its great and growing population is largely official The American law-courts are of two kinds—those belonging to the several states and those of the federal government In the latter class is the famous Supreme Court of the United States at Washington which says the last word upon all constitutional disputes and upon the validity of all legislation (whether state or federal) The trial of the A M A is proceeding at Washington in one of the district courts of the federal system American forensic procedure often strikes English observers as old-fashioned , but the deliberate efforts to secure a jury which will eschew all bias are doubtless necessary in this case where so many Washingtonians may be members of G H A or patients or friends of the defendant doctors The court has patiently examined all the prospective jurors to find out whether they are subject to any such influence and even whether they (or members of their families) are officials of the United States, the prosecutor Jurors have been asked by the court if they or any members of their families have ever been sued by a physician, or if they have ever "had any occurrence which has aroused any antagonistic feelings towards a doctor, a physician, or any group of doctors or physicians" , had they formed any opinion about the right of hospitals to select doctors for their staff, or about the right of doctors to organise themselves in associations with rules and regulations governing professional practice ? And so on

To return to the trial, the two opening addresses for the prosecution were followed by a spirited opening address by counsel for the defendants He explained the constitution and standards of the A M A , its formulated ethics were derived, he said, from an Englishman named Thomas Percival who in 1803 framed them for the College of Surgeons in the City of Manchester in England The code, based on the oath of Hippocrates, had been proved to be the only safe standard for distributing medical care to the public and the patient The great developments in medicine, outlined by the prosecution, had been due to the efforts of the A M A to prevent the destruction of progress by quacks and charlatans who advertised their wares in such language as the G H A was using—"You can't sell medical service as you sell baked beans"

PLAN TO CHECK RHEUMATISM

RHEUMATIC disease, though widespread, painful, disabling and responsible for great economic loss, has never roused public sympathy or conscience as keenly as tuberculosis, cancer or venereal disease For one thing it presents no clear-cut picture , how can it, when the word has been used to cover at least two, and probably more, distinct disease entities ? The acute and subacute rheumatism of childhood, manifesting itself as rheumatic fever, tonsillitis, chorea and growing pains and bringing in its train heart damage, invalidity and often death, has probably nothing in common with the disabling muscular rheumatism, fibrositis or osteo-arthritis of later life , and these again may prove to be distinct from rheumatoid arthritis, and even from each other To devise a plan which will ensure the diagnosis, treatment and aftercare of all these is not simple, but Lord Horder, in collaboration with the Empire Rheumatism Council, has some practical suggestions to make[1] Their plan was almost ready in 1939 but it seemed

Any method of inducing labour must be assessed by its comparative speed, certainty and morbidity-rate for both mother and child Out of his 115 cases, Playfair reports 4 failures, and the average time between injection and the onset of labour was roughly 29 hours—slightly longer than after artificial rupture of the membranes His corrected fœtal mortality for uroselectan induction was 3 6%, while a similar series of controls, in which artificial rupture of the membranes was performed, had a fœtal mortality of 4% His incidence of puerperal pyrexia was 5 out of 115—1 due to tonsillitis, 2 to urinary infection, 1 to red degeneration of a myoma and 1 to a local infection of an episiotomy When it is considered that none of these was a true case of uterine infection this method compares favourably with other surgical methods, where an average infection rate of 10–15% is to be expected One point strongly in favour of uroselectan is that it is no contra-indication to a subsequent cæsarean section, which was successfully performed in 2 of Playfair's cases, whereas it is a bold obstetrician who would consider section after surgical induction The length of the various stages of labour was not appreciably different when uroselectan was compared with the other methods of induction

THE BRAIN-STEM IN CONCUSSION

Denny Brown[1] lately called attention to the cases of head injury which, after a latent period, develop collapse associated with bradycardia, headache and a variable degree of neck rigidity The blood-pressure remains normal and the clinical developments do not seem to be directly related to raised intracranial pressure or to subarachnoid hæmorrhage, though the latter was present in some cases The eventual recovery of Denny-Brown's patients made it impossible to study the underlying pathology, but, mainly on account of the prominence of bradycardia, he tentatively ascribes the condition to contusion of the medulla oblongata Slowing of the pulse was associated with other evidences of vasomotor instability and was observed only with the patient absolutely at rest, any activity was always followed by acceleration of the pulse, which was maintained for 2–3 hours after return to bed Denny-Brown's experience of gunshot wounds of the head in the present war, taken in conjunction with records of similar cases in the war of 1914–18, leads him to postulate that the entry into the skull of small fragments of metal communicates little momentum to the brain as a whole, but the high velocity of such fragments transmits pressure to the foramen magnum and leads to concussion or contusion of the medulla oblongata This suggestion may turn out to be fundamentally important in the pathology of concussion in general, and may explain why so many victims of head injury die within the first 24 hours The brain in these subjects often shows an amount of trauma which seems insufficient to have caused death In this connexion Denny-Brown and W R Russell[2] have found, by experiments on cats under Nembutal anæsthesia, that concussion, even resulting in death, associated with cessation of respiration and rise of blood-pressure without macroscopic lesions in the brain stem, may be produced by a blow when the head is free to move and yet will not be produced by the same blow when the head is firmly fixed, they justly argue that the concussion must therefore have been due to the acceleration imparted to the nervous tissues Possibly microscopic examination would have supplied further information

Schaller, Tamaki and Newman[3] have studied the distribution of petechial hæmorrhages by serial sections in a number of rats which were severely but not fatally concussed The petechiæ were widely distributed throughout the brain but were noted particularly in the deeper tissues, including the basal ganglia and the brain-stem There were no large hæmorrhages or softenings In animals surviving for long periods such foci showed evidence of repair These workers stress the vascular basis of concussion and trace the production of petechiæ from vasodilatation leading to stasis, anoxæmia and permeability of the vessel wall They found no evidence of damage to the myelin sheaths, no gliosis remote from the vessels, and no progressive pathological involvement of the vascular system Although they did not lay any special emphasis on damage to the brain-stem their finding of petechiæ in this situation in so many examples fits in with Denny-Brown's conception Possibly the control of consciousness may turn out to be situated in this part of the brain Thus Cairns,[4] in his account of gunshot wounds of the head in 1940, says "it is remarkable that cases of foreign body penetrating the frontal and parietal lobes showed no loss of consciousness, whereas a foreign body passing through the petrous bone into the cerebellum produced unconsciousness which lasted several days Is the unconsciousness (concussion) of closed head injuries of civil life due," he asks, "to commotion of the whole brain, or to damage to some part of it, such as the brain stem ? "

SOCIAL HYGIENIST WANTED

Sir Drummond Shiels, who has been medical secretary of the British Social Hygiene Council for some years, is retiring from this post, though he will still act as medical adviser As announced in our advertisement columns, the council are in need of a successor, who must be a doctor familiar with the problems of sex education and of venereal disease Much of the council's work is now concentrated on teaching young people between 16 and 25 the elements of sex knowledge and guiding them on sex behaviour The medical secretary's duties, which are part-time, are to travel on the council's behalf in the provinces, discussing their difficulties with medical officers of health and V D officers, giving lectures, and keeping a professional eye on the council's courses of instruction

---

Dr J E A UNDERWOOD has been appointed senior medical officer to the Board of Education in succession to Dr J Alison Glover, who reaches the age of retirement on April 10 Dr Underwood had served for four years in the R A M C and was an experienced school medical officer before joining the board's staff in 1925 In that year he was secretary to the Departmental Committee on defective vision in children and since 1928 he has been chiefly responsible for advising the board on schools for blind and deaf children The 1931 report on partially sighted children was largely his work and he represented the board at the world conference in New York on the welfare of the blind He takes up his new responsibility with a wide knowledge of the school medical service generally and of the work of special schools

Dr JOHN SMYTH MACDONALD, F R S, who died on Saturday last at Bridge of Allan, held the Holt professorship of physiology at Liverpool University from 1914 to 1932 after having occupied the similar chair at Sheffield for 12 years His work on the function of muscle and nerve was widely known He was in his 74th year

THE following have been appointed honorary physicians to the King for three years Sir HENRY BASHFORD, chief medical officer at the Post Office, Sir WELDON DALRYMPLE CHAMPNEYS, deputy chief medical officer at the Ministry of Health, Dr J M MCCLOY, chief medical officer at the ministry of home affairs for Northern Ireland, Prof W W C TOPLEY, F R S, head of the emergency public health laboratory service, Dr R VEITCH CLARKE, medical officer of health for Manchester, Dr W G CLARK, medical officer of health for Edinburgh, Dr JAMES FERGUSON, medical officer of health for Surrey school medical service from 2% in 1926 to 0 77% in 1926 This scheme provides supervisory centres to which children suspected of rheumatic diseases are referred. Children who are fit for ordinary education return to school but are kept under supervision; those who need treatment are referred to rheumatism units outside London, and those cardiac cripples who can benefit by appropriate education (about 16%) are sent to special schools In a standard year there are usually about 2000 children attending such schools

---

A similar scheme in its full range could be applied by local authorities to all state schools, and impoverished areas should receive grants from national funds for the purpose.

RESEARCH

There remains research the most urgent need of all For this the Empire Rheumatism Council is willing to assume responsibility, with what help can come from the Medical Research Council, the various medical research foundations and the medical schools In addition, the treatment centres, once in action, would become a source of statistics capable of answering many of the questions still left teasingly open

MEDICINE AND THE LAW

Aortic Disease an Accident

In the case of Tyler *v* New Hucknall Colliery, mentioned lately in this column, the Mansfield county-court judge held that the perforation of a duodenal ulcer was not an accident within the Workmen's Compensation Act More recently in *Tennant v Coppice Colliery Co* the Walsall county-court judge decided in the workman's favour where a blow, received in the course of his work was said to have accelerated the disease of the aorta The man worked for two days afterwards, stayed away on the third day, gave up work after a brief attempt on the fourth day and went to hospital where he was X rayed He died suddenly about a fortnight later The pathologist who made a post-mortem examination for the purpose of the inquest gave evidence before the county-court judge which was consistent with the death being in no way due to the blow There was, said two medical witnesses a failure of the blood-supply in consequence of the blocking of the arteries The calcification of the aorta was exceptional; the calcareous matter had been accumulating over a long period and the accident had no effect upon it The judge however pointed out that the employers had been unable to explain why the workman, having had nothing wrong with him before the blow had suffered pain after it Drawing the inference that the accident had markedly accelerated the development of the condition of the aorta he awarded £600 compensation

Inadmissibility of Coroner's Verdict

In Tennant's case, mentioned above, the coroner's verdict had attributed death to the occlusion of the right coronary artery The verdict of an inquest is, of course of no value in other courts This was clearly illustrated in the tragic case of Pollock *v* Pollock this year Last June a devoted husband, worried and oppressed by the war news, shot his wife and then shot himself His wife had left her estate to him, but the law does not allow a murderer (or anyone who claims through him) to profit by his crime The husband had killed his wife If he was insane at the time, it was not a murder, but the burden of proving insanity lay upon the husband's representatives and, the husband being dead they were not likely to be able to discharge it The wife's executors applied to a Chancery judge for advice They were told that they should act on the assumption that the husband had murdered his wife, and they should not hand the wife's estate over to the husband's representatives A coroner's verdict had recorded that the husband killed his wife while his mind was unhinged, but Mr Justice Farwell was unfortunately prevented by law from taking note of the facts determined by the inquest

Workman's Denial of Disease

A workman, on entering a mining company's employment, untruthfully made a written statement that he had never suffered from nystagmus The disease appeared and he qualified for compensation on the certificate of the examining surgeon who fixed the date of the disability The company exercised its right to have the workman examined by a surgeon to whom the patient admitted that he had previously suffered from nystagmus This surgeon reported the disability to be a severe case and recorded the patient's admission. The Workmen's Compensation Act purports to disqualify a claimant who has made a false denial on entering employment The company nevertheless paid the man compensation at the full rate until, many months later, payment was discontinued on the ground of the false representation What the Act says (in paragraph (*b*) of section 43 (1)) is that "if it is proved that the workman has, at the time of entering the employment, wilfully and falsely represented himself in writing as not having previously suffered from the disease, compensation shall not be payable" The county-court judge held that there was false and wilful misrepresentation, but he also held that the paying and receiving of compensation formed a binding and concluded agreement between the parties and that all questions of liability were thereby settled The Court of Appeal has upheld the county court Section 43 (1) (*b*) is not an absolute prohibition. Those initial words "if it is proved" create an issue of fact for an arbitrator to try This issue can be the subject of an agreement between the parties If the employers chose to pay compensation without availing themselves of such precautionary safeguards as the lawyerlike words "without prejudice," and if they offered no explanation, their generosity was fatal

SCOTLAND

POLISH MEDICAL FACULTY IN EDINBURGH

THE discussions which have been in progress between the British and Polish governments and the university and municipality of Edinburgh regarding the institution of a Polish medical faculty in Edinburgh achieved their end in the McEwan Hall of the University on March 22 Monsieur Wladyslaw Raczkiewicz, president of the Polish Republic, formally constituted the faculty and named its members Sir Thomas Holland, vice-chancellor of the university, said that though wars had occurred in every century, countries had been invaded and local institutions had been brought under the control of conquerors never before, since their rise in the fourteenth century had universities in any country been ruthlessly destroyed For precedent it was necessary to go back another eight centuries to the time when the schools of the Roman Empire were swept away by other Teutonic savages, who by that means inaugurated the Dark Ages Among the first of the universities founded with the revival of learning was the Jagiellonic University of Cracow which maintained its reputation as a great home of liberal education for just 540 years until, along with its sister universities, it was lately destroyed The Polish universities had produced poets and historians of great distinction of whom, because of our linguistic limitations, we knew too little But of those Poles who had published their works in the universal language of music everyone knew of Chopin and Paderewski The scientific and a wider world, too, revered the names of two famous Cracow graduates, Nicolaus Copernicus who in a double sense revolutionised astronomy in the sixteenth century, and Marie Sklodowska, known to fame as Madame Curie Round a nucleus of a dozen professors and about fifty students he said, would grow a school of medicine so vigorous that its Edinburgh cradle would barely be large enough to hold it until it was free to return again to its native land, there to inaugurate a new era as the foundation faculty of the rejuvenated Universities of Poland Sir John Anderson conveyed to the new faculty the best wishes of the British Government, in reply Professor Kot the Polish minister of the interior, traced many academic associations between Poland and Scotland in the past Prof. Sydney Smith, dean of the faculty of medicine, also welcomed the newcomers Professor Jurasz, the newly appointed dean of the Polish faculty, looked forward to a time when they would all meet as free men, in free doubtful whether the time was then opportune to publish it, now Lord Horder feels that "considerations of humanity, of national safety and true economy plead for some immediate effort to check rheumatic disease" What he has to say is addressed to all who are interested in public health, and he writes without using unnecessary scientific terms

THE PUZZLE

In stating the extent of the problem he notes that adults with rheumatism in England and Wales can be conservatively estimated at over a million, and the economic loss among insured workers at £17,000,000 a year Cases of juvenile rheumatic disease, calculated on the basis of the statistics of the L C C medical service, he puts at 200,000 in Great Britain

Our knowledge of the ætiology of rheumatic disorders is still vague Discussing possible factors in its causation, Lord Horder shows how far our questions were ahead of our knowledge, and pleads on almost every page for more research In juvenile rheumatism we can say that infection, bad housing and perhaps heredity, defective diet and scanty clothing play a part In adult rheumatic disorders occupations figure largely, especially those which invite small injuries, bruising, repetitive movements and cramped attitudes Climate, of course, does its share "the old man carries the almanack in his bones" Other factors suspected of contributing are focal sepsis, glandular dystrophy, some inherited or acquired biochemical flaw, diet, heredity, mental or emotional disturbance, housing, injury and geological conditions Against most of these can be set a question mark, we do not know how much or how little they act as rheumatic provocants Uniform record-keeping and a thorough study of cases should settle some of these questions, others require intensive work in the laboratory

WHAT CAN BE DONE

Little as we know about the cause of diseases grouped under the heading of rheumatism we can—contrary to common belief—do a good deal for them Juvenile rheumatism presents a problem of its own, calling for early diagnosis, determined treatment and steady aftercare For the chronic rheumatic diseases of adults much can be done by physical treatment in its several forms, massage, pyrotherapy and shock therapy, physical exercises, drug therapy, orthopædic measures, colonic lavage and vaccines Lord Horder assesses the relative value of the various remedies cautiously but is able to quote figures from many treatment centres showing the excellent results obtained by a judicious and persistent attack on the symptoms, no claim is made that any treatment now in use strikes at the unknown cause

At the Devonshire Royal Hospital 3062 patients were admitted in 1937–38, of whom 2617 were discharged cured or much improved At the Royal Mineral Water Hospital at Bath 62% of patients were cured or relieved in the eighteenth century, 88% in the nineteenth, and 95% (so far) in the twentieth The British Red Cross Clinic, treating out patients only, claims that 60 3% of patients are freed from objective symptoms and 29% improved, leaving a balance of 11% An American treatment centre reports that 75% of cases are cured or improved, 20% are refractory and 5% hopeless

This is an encouraging picture, suggesting that if we can place appropriate treatment within reach of all who need it the practical problem is largely solved

THE PLAN

Lord Horder suggests that this could be done by setting up, on a regional basis, specialised treatment centres each of which would supervise a number of local centres in its own area The special centres would diagnose and treat both inpatients and outpatients referred by local treatment centres, hospitals or private doctors Each special centre would be under the charge of a whole-time permanent medical officer with special experience of rheumatic disease, and would be staffed by qualified assistants, paid or voluntary, including workers in every branch of physical therapy, radiology, hydrology and chiropody The centre would also have access to a full consultant staff of physicians and surgeons, including an orthopædic and manipulative surgeon, a dental surgeon, a gynæcologist, a rhinolaryngologist, a pathologist and a radiologist Ten to fifteen such centres, it is estimated, would be sufficient for Great Britain

Local treatment centres should of course be much more numerous, and would treat outpatients only, each centre being equipped to deal with anything from 50 to 250 patients a day, depending on local needs The local centres would provide massage, remedial exercises and the simpler heat and electrical treatments The staff would be trained in massage, one of them having in addition a qualification in hydrology, and one a full nursing qualification Patients would be received on the recommendation of their own doctor, remaining under his treatment for everything except their rheumatic symptoms Is it, perhaps, questionable policy to divide the patient up according to his diseases in this way? In theory it seems unsound and though in practice it might work out fairly well, it deserves careful preliminary consideration The medical officer in charge of a local treatment centre would not necessarily be on whole-time service but might have charge of two or three centres, he should have special experience in the diagnosis and treatment of rheumatic disease Through close liaison with the special treatment centres, consultants would visit the local centres when their advice is needed

One aim of the plan is to educate the patient in the understanding and care of his own disease, and this will be achieved at the special treatment centres, by lectures, and films, which will instruct him in the importance of such things as diet, rest, clothing and exercises It will even be possible for some patients to carry on a simple course of treatment at home, thus avoiding frequent visits to the local centres, in this they will naturally need the supervision of skilled social workers This system has worked well as organised by the Mayo Clinic arthritis department

Another aim of the plan is to train sufficient medical personnel in the diagnosis and care of rheumatism by arranging special postgraduate courses and lectures, not only for those who are staffing the clinics but for school medical officers and any other doctors who are interested Some of the special centres, it is hoped, will be attached to university medical schools, and the medical staffs of all of them should be equal to the teaching task required of them

The plan will divide patients into three sections a large group who after a short period of institutional treatment and an educational course would be able to carry on home treatment with periodic visits to a local centre, another large group who could attend regularly at a treatment centre, and a small group who would need inpatient care or treatment which could only be given at a special centre

The cost of the scheme would not be as great as appears at first sight The special centres would be accommodated in existing hospitals, clinics and spas which could provide the necessary equipment, the local centres could be housed in hospitals, pit-head baths, public baths, welfare premises of factories or if necessary in huts put up for the purpose

The cost of treatment could be met in full by those who could afford it, at a concession rate (for example, through the Hospital Saving Association) by those with less means, and by an extension of the National Health Insurance system for insured workers At present there are very few rheumatism treatment centres at which approved societies can arrange treatment for their members, and it is scarcely just that a man in London or Sheffield should have opportunities for treatment which are denied to his fellow in some other part of the country All contributors, as Lord Horder points out, should be on an equal footing He sees no need for elaborate centres or equipment, believing that research will shortly give us fuller knowledge and thus more control of the diseases treated, and that early diagnosis and treatment will reduce the morbidity from rheumatism

RHEUMATIC DISEASE IN CHILDHOOD

The problem presented by juvenile rheumatism is of course entirely different Here Lord Horder believes the best hope lies in a national plan on the lines of the L C C rheumatism scheme, which has helped to reduce the incidence of recorded heart disease in the L C C

In England Now

A Running Commentary by Peripatetic Correspondents

WE still don't seem to be getting full value from the visiting-team system, and the faults are not wholly on either the hosts' or the visitors' side. When a hospital is threatened with a big take-in it bursts with pride over its unlimited capacity. "Want assistance? Good Lord, no! We can deal with anything. Ask for a visiting team—surgical, resuscitation or nursing? We should think not!" Then when after 48 hours' continuous work they at last send for help the team finds them tired and cross; nobody receives them or tells them what they are wanted for or where things are kept. There is no cup of tea, no handshake. The visiting team, on their part, making no allowances for exhaustion, utter loud criticisms of the lack of welcome, of house-men and nurses, and of the deference which "consulting surgeons" are used to. Keenness is all very well, but no-one is going to do his best work when he is asleep on his feet, and it is mere foolishness to try when relief can be got. The hospital staff—medical, nursing, or lay—should knock off before they are compelled to by sheer fatigue, and those in charge should realise that their job is to foretell when this limit is likely to be reached and ask for help in time. When the team arrives there will then be juniors fresh enough to serve the strangers and make them free of the hospital's resources. The visiting team can help by putting themselves in their hosts' place, mentally as well as physically, and by bringing with them some dog's-bodies of their own, students or probationers, to fetch and carry.

* * *

The lights in the train suddenly went out, and we knew that there was an air-raid in progress, but we ran on at a good pace in the bright moonlight, and I got to my home town only a little late. The station was in darkness, save for the shaded light belonging to the ticket collectors, and so we passed out into the streets to the noise of gunfire, the zoom of planes and the frequent crumps of bombs. There were no taxis, and I did not care at all for the prospect of walking the two or three miles home; so I decided to hurry along to my hospital, which was a good deal nearer, and give a hand in whatever was doing. I caught up with a soldier—an "old sweat"—and we walked in step together. "What a bloody party," he said as a sudden brilliance lit up the sky, and we saw a "Molotov chandelier" dropping down. "That's so-and-so," he went on, pointing to a huge fire behind us, "Jerry knows where he bloody well is." (I found out later that it was nowhere near the important so-and-so.) Our ways parted and he clumped off into the moonlight, with a five-mile walk in front of him.

At hospital no casualties had yet come in, and my houseman took me to the residents' room for tea and toast. One of the other housemen came in from his shift of fire-watching, and we discussed where the fires in the town might be. Then came the news that a casualty had come in, and we trooped down to the reception hall. It was rather an anticlimax to find that he was an old man with a cerebral hæmorrhage. But soon a real air-raid victim came in—a man who, standing at his door watching for incendiaries, had been thrown out into the street by the collapse of the house under a H.E. bomb. He had a fractured tibia and fibula, and he was covered with dust and dirt, his face as black as a coolie's. The next was a middle-aged Roman Catholic priest who, being unable to find a bag of sand in the street, had jumped on an incendiary bomb to put it out and had found it explode as he landed on it. Then came a couple of walking cases—bruised ribs from falling bricks, and a fire-watcher whose tendo achillis had been trodden on by a horse. He sat indignantly in a chair, nursing his sore heel and appealing to me. "Why need the chap have interfered with the rope?" he said. "What chap and what rope?" I asked. "Well, when the bomb fell, I went to get the three horses out of the stable, and I'd got two out all right, and then this fellow comes along and grabs hold of the rope and mucks everything up. He'd no cause to get hold of the rope, I was managing it all nicely." "Were they your horses, then?" I asked. "No, they'd nothing to do with me, you know, but I knew they were there and had to be got out and I was managing nicely. He'd no cause to get hold of the rope." I looked at his foot, rather for form's sake, because as a physician I know little about these things; obviously he was not badly hurt, only bruised and sore. "Just like another famous chap," I said. He looked at me quizzically, "What famous chap?" "A fellow called Achilles." "Never heard of him," he said, with the generous air of letting me have my little joke, and an obvious relief that things were not beyond a joke.

An air-raid warden white with dust, who had brought in the man with the fractured tibia, then tackled me. "Eh doctor, d'you think there's any chance of my getting my best Sunday tie back again, it's round that first-aid splint? I expect I'll get a George Medal for tying up that leg! But I'd like that tie back again, I feel so untidy without a tie round my collar." Even the fractured tib.-and-fib. on the stretcher ("Records" were just finishing his particulars) had to smile. Then came an elderly woman from the same incident, with great raw gaps of flesh torn out of her arm and leg, badly shocked, with a strange, uncanny look of puzzled questioning. Soon more cases were coming in, and I went along to the resuscitation ward. Already the tib.-and-fib., the priest and the elderly woman were being got into bed and warmed up. More cases arrived in the ward. There was an oldish man with a head wound, his clothes wringing wet, profoundly shocked, dazed and shivering. I never found out why he was soaked and he could not tell me; but when I gave a hand with the surprisingly awkward task of taking off his wet and clinging trousers, he roused up and said angrily, "Here, what are you doing that for?" Two policemen out of a posse of four who had been sent out to clear the streets round an unexploded bomb were carried in, nearly dead, with the skin blasted from their faces. One of our policemen had been blown a distance of fifty yards or more, and three days later they were still finding in the mass of rubble pieces of uniform and limbs belonging to the other two, as well as the bodies of other poor folk who had been buried. Happily our two constables still survive.

A middle-aged warden carried in a bundle, telling us that it was an unidentified child rescued from what had been a group of modern tenement dwellings. It was a little boy about a year old, his face waxen where it was not black with grime, with a pulpy wound on the back of the head, and a great gash across the forehead. For several hours we watched the baby's life ebb, and then slowly come back again with the appropriate resuscitation measures. An auxiliary fireman came with one of his mates, who had a deep wound into the knee-joint. They had been fighting one of the big fires in the town, playing their hoses from an adjoining building. An H.E. bomb hit their building, and my informant found himself standing on a beam high in mid-air. He grabbed at his pal and held him for a second or two; when the man slipped out of his grasp, he fell on the debris of brick and building and not underneath it, and this saved his life, for three or four other A.F.S. men were crushed to death on the spot. His friend turned to me with savagely clenched fist. "Shooting's too good for That Man," he said.

All this time confident young registrars and housemen, sisters and nurses were getting on with their various jobs, and the emergency theatre was now in action. The tib.-and-fib., the priest, the elderly woman and others were back in bed, recovering from their anæsthetics. I was in the anteroom of the theatre, having a cigarette with my houseman, when suddenly there was a heavy explosion. My houseman dived under the theatre trolley, and rather like a slow-motion picture I dropped on to the floor on my face, listening to what sounded like the roof falling in, and foolishly aware that after all I had not even the cover of the thin aluminium top of the trolley. Then we got up again, and looked around the hospital to see where it had been hit. But it had not been hit; a very heavy bomb had landed on a building across the way. I rushed up to my own wards; glass and dust were all about the corridors, all the windows of one of my wards were broken and some in the other, but the patients were all safe. The night nurses had the situation in hand, the patients were steady and some could even crack a grim joke about it. It was the same throughout the hospital—glass and dust and soot, no casualties and no panic.

countries, in a free Europe The honorary degree of LL D was conferred on President Raczkiewicz

It was subsequently announced that the public-health committee of Edinburgh town council had approved a proposal that, in connexion with the Polish medical school, Polish patients should be treated at the Western General Hospital The Department of Health for Scotland was prepared to allocate up to 150 beds under the Emergency Hospitals Scheme for the purpose The beds set aside for Polish patients would be staffed by Polish doctors and tended by Polish and British nurses Thus the Polish school receives an important addition to the teaching facilities which are already available, and indeed in use, in the Royal Infirmary

PARATYPHOID OUTBREAK IN THE HIGHLANDS

A considerable outbreak of paratyphoid fever has occurred in the counties of Moray, Nairn, Inverness, Ross and Cromarty The primary wave is largely over and a secondary wave is now expected The incidence of the epidemic has been greatest in Ross-shire, particularly at Alness, where Bridgend School has been closed It is thought that the organism has been spread by food rather than by the water-supply, but so far the source has not been identified

BRITISH ORTHOPÆDIC ASSOCIATION

THE postponed 1940 annual meeting* of this association was held in Oxford on Jan 3, under the presidency of Prof T P MCMURRAY, when the following short papers were read

Mr. A L EYRE-BROOK and Mr K H PRIDIE (Bristol) had reviewed by clinical and X-ray examination the progress after one year of 47 patients out of 75 treated for *fracture of the neck of the femur* by manipulative reduction and the insertion of a Smith-Petersen nail (Hey-Groves technique) Bony union was proved in 58% of patients and in the whole series of 75 there had been a fatality of 5 3% Aseptic necrosis of the capital fragment had occurred more often in patients under thirty The importance of the fracture shaft angle of Pauwels was emphasised If this angle was low (below 30°) the results from nailing alone were poor and a fibular graft should be inserted as well

Mr NORMAN ROBERTS'S (Liverpool) description of the indications for *excision of the patella* was based on a series of 20 cases He discussed the uses of the patella and emphasised the following points —

1 Recovery of function after excision is not so rapid as is often thought, though it is more rapid than after suture of the patella

2 After excision flexion movement is usually full or is possible at least to the right angle , there is often a limitation of full extension and the quadriceps is often weaker than normal

3 Excision is advisable in all comminuted fractures in both young and old patients , and in transverse fractures in middle aged and old patients

4 Transverse fractures in young patients should be sutured If the fragments are very unequal in size it is easier to excise the smaller fragment and to suture the rectus or patellar tendon efficiently to the larger fragment

5 Derangement of the knee due to recurrent dislocation of the patella cannot usually be cured by excision of the patella

6 Good results sometimes, but not always, follow excision in osteoarthritis of the knee, particularly if the arthritic changes are mainly in the patello femoral compartment of the joint

Mr G E THOMAS (Liverpool) had achieved *correction of scoliosis* in 16 patients , usually by recumbency on a Thomas frame with longitudinal traction and counter traction applied via the head and legs and three-point pressure on the apex of the convexity and the extremities of the concavity. To exert lateral pressure special pads operated slowly by a screw mechanism of the Thomas wrench type was employed Failure to achieve correction had occurred in very high and very low curves, in severe long-established curves, and in those cases in which there was gross rotation out of all proportion to the lateral curvature

Mr W S DIGGLE (Liverpool) reviewed a series of *fractures of the external tuberosity of the tibia* For those cases in which there was gross comminution and depression of the fragments he had found open operation, replacement of the fragments and screw-fixation the most effective treatment Most of his patients treated in this way had been able to return to work in about six months

Mr G K MCKEE (Norwich), who spoke on the treatment of *compound fractures of the leg*, advocated fixed skeletal traction on a Thomas splint for both tibial and femoral fractures, simple and compound For tibial fractures a Steinmann pin was inserted transversely through the upper tibial fragment and through the os calcis or the lower fragment The pins were fixed firmly, after reduction by manual traction, to the lateral bars of the Thomas splint by a special clamping device For femoral shaft fractures one pin below the fracture, fixed in a similar way to the Thomas splint, was employed To avoid undue pressure on the ischial tuberosity or groin the splint was tied to the end of the bed which was then elevated The advantage of this method, in contrast with the closed-plaster technique, was discussed in the light of its success in 30 compound and 20 simple fractures

Mr F C DWYER (Liverpool) considered that *Kier bock's disease* is probably due to a fibrosis, resultin usually from trauma, of the dorsal ligaments attached t the carpal semilunar From an experience of 34 patients in 10 of whom the damaged semilunar had been removed Mr Dwyer felt that conservative treatment offered th best results in a condition which always left a permanentl damaged wrist

Mr J Z YOUNG (Oxford) outlined the preliminar results of the experimental work now in progress a Oxford on *nerve regeneration and nerve grafting* i rabbits At the start he warned against applyin completely to man experimental findings, even thoug they had been very accurately demonstrated in animals The need for a qualitative method of comparison betwee different procedures for nerve repair was emphasised The rate of growth of new fibres was adopted as a criterion and a method of estimating it developed The rate for rabbits, found to be about 4 mm a day, was the same in all nerves and approximately the same at al levels Certain suture material gave severe reactions—e g , catgut and pigmented silk White silk, woman's hair sutures, and fibrin "glue" produced the least reaction Return of function was often rapid and rapid recoveries occur even after full Wallerian degeneration They are not due to physiological interruptions such as arise after ischæmia but which clear up even more rapidly Mr Young pointed out that the delay between interruption and recovery of a nerve's conduction has three parts

1 In the junction scar—probably about 20 days in man

2 In the nerve itself, during the growth of fibres down it, which probably takes place at the rate of 2 5 mm a day in man

These two phases comprise the anatomical delay

3 In the muscle—the functional delay—about 40–60 days in man The delay in the muscle seems to be shorter if the muscle has been denervated only for a short time, a finding strongly in favour of early suture

The problems of bridging gaps were discussed It had been demonstrated that nerves could not be stretched suddenly more than 10% of their total length , and that increase in length from gradual stretching was probably due to growth in length of the nerve rather than to stretching Autografts had given most success in rabbits and there were some encouraging results from homografts

---

* This report was delayed by enemy action

MEDICAL SUPPLY ASSOCIATION, Ltd , draw attention in their catalogue to a new electromedical switch-table (Universal Electrostat, series III) This incorporates a metal rectifier and is claimed to have none of the disadvantages of motor generators or valve rectification. A treatment-table (Panapoise) combines maximum stability in all positions with wide range of adjustment and ease in movement of individual sections Their featherweight Schnee baths are constructed of metal with moulded rubber linings , they are unbreakable and should prove much easier to handle than the cumbersome earthenware type in common use.

Public Health

From the Annual Rèports

TUNBRIDGE WELLS

Dr F. C Linton's report of the borough of Royal Tunbridge Wells is fairly comprehensive Tunbridge Wells covers 6034 acres, has a population of about 35,000 and in 1939 its birth-rate was 11 9 and its crude death-rate 15 6, which on multiplication by the com- rability factor of 0 73 becomes 11 4 Cancer mortality as 2 1 and tuberculosis mortality 0 37 Here we have nother "artificial" population, departing from normal the reverse way to that of Dagenham Comparison the two brings out the truth that differences in health atistics which occur naturally in populations of different mpositions are much greater than those between the est and worst services, or the healthiest and most nhealthy years and places which are met with in ntain In the closing years of the last century the ge-distribution of all deaths in Tunbridge Wells was oughly one-fifth under one year, two-fifths between e and 65 and two-fifths over 65 years of age In 939 the distribution was 9 under one year, 164 etween one and 65, and 379 over 65 years of age he infant-mortality rate in 1939 was 21, the lowest ecorded in the borough and less than half the average ate of 46 1 for the past ten years So many districts ave recorded infantile mortalities below what we ormerly feared was the irreducible minimum that these xtraordinarily low rates cannot be due to chance They re the resultant of low rates for deaths from all the rincipal causes including malformations

LIVERPOOL

Fourth in population of the cities of Great Britain, and itself the metropolis of the port of Mersey, Liverpool has always been of particular interest to students of public health, for it was the first place to appoint a medical officer of health and at the outbreak of the present war was the centre of the controversy over the reform of units of health administration Its population at present is 822,000 but it is not a self-contained unit, being continuous with Bootle on the north and joined to, rather than separated from, Birkenhead by the Mersey The annual reports of Liverpool have always been comprehensive, and though that of Dr W M Frazer for 1939 is cut down to about half, it is still one of the most complete local reports for that year Reduction has been steady in all causes of infant death since the beginning of the century, but greatest in diarrhœal diseases, from 57 to 7 , in tuberculosis from 6 to 0 8, and in nervous diseases, from 22 to 8 7 ; the last presumably includes convulsions The least reduction was in deaths due to prenatal causes, from 51 to 33 Since 1871, the percentage of total deaths due to infectious diseases, other than diarrhœa and influenza, has fallen from 19 2 to 2 7 , that of tuberculosis from 13 5 to 7 , that of respiratory diseases from 20 2 to 11 1 , that of diarrhœal diseases from 10 to 4 5 On the other hand, the percentage of all deaths due to cancer has risen from 1 4 to 12 1 The reduction of deaths from what were formerly called zymotic diseases has been almost regular during the 70 years , that of diarrhœal diseases started only at the beginning of the present century, and that from respiratory diseases only since 1930 This illustrates the course of preventive medicine during the period Hygienists in 1870 knew that fevers could be prevented , it was not until the severe epidemic of infantile diarrhœa in 1899 that they were convinced that that disease too could be prevented, and the prevention of respiratory diseases, other than phthisis, did not seem to be practicable until modern health practice had made considerable progress The increase in cancer is admittedly a black spot on preventive medicine, even though the increase is partly artificial being due in large measure to the higher proportion of old people in the population and improvements in diagnosis Preventive medicine never assumed that it could prevent us from dying , it was determined to prevent us from dying young and has largely succeeded in doing so But it did not pay much attention to the aged until recently ; at the outbreak of the present war it was considering what could be done to help the aged to die comfortably.

In 1939 there were 8 cases of anthrax in Liverpool ; all were treated with serum and all recovered Only 1 was on the arm, 4 were on the back of the neck and 2 on the temple ; in view of this distribution, the success of treatment is remarkable A comprehensive table of the comparative case-rates of diphtheria, 1933–39, in inoculated and uninoculated subjects brings out that in the uninoculated the annual incidence in persons under 10 years of age was 11 3 per 1000 ; in the inoculated it varied from 1 5 in those treated by F T to 3 in those treated by A.P T The numbers are sufficiently large to give significant results The unfavourable results with A P T may have been due to the "one-shot" method, which has now been discarded. There were 70 cases of cerebrospinal fever, about the average annual number in recent years , the fatality was 40%, the lowest in the past 10 years, but still much higher than what is expected with recent methods of treatment Encephalitis lethargica has died out ; the last notification of an acute case was in 1937 and the last death in the acute phase in 1934 , since 1935 there have been 51 deaths of old cases

SOMERSET

The physiography of Somerset is as diverse as that of any county in Britain but its industries, though varied, are mainly agricultural Those who know Somerset will be surprised to hear that, judged from the comparable death-rate, which in theory is a good guide, Street comes out as the healthiest district Ilminster, which comes out at the bottom of the list had no infantile mortality, a distinction it shared with Wells and Wellington The county now has five clinics for mental cases under the Mental Treatment Act, 1930 Although 118 sessions were held, the total number of patients seen was only 73, which leads Dr Davidson to say that the facilities available are being *comparatively* little used by practitioners. Neither the general public nor the medical profession has yet got acclimatised to the Mental Treatment Act , this is hardly surprising seeing that the act is but ten years old *and* reverses what may be called the ideology of mental disease which had been current in the country for centuries Both patients and doctors are inclined to look on mental clinics as *means* of getting people into institutions. instead of keeping them out, which is what the clinics are intended for.

BERMONDSEY

Dr D M Connan in his report of this metropolitan borough tells us that 90 8% *of fatal* cases of phthisis were notified prior to death, but of fatal other tuberculosis only 25% were notified , there were, however, only 4 cases of the latter In these days, apart from phthisis the only manifestation of tuberculosis in which direct fatality is at all common is meningitis, which for obvious reasons is *infrequently* notified before death In Bermondsey the Minister of Health has sanctioned the free supply of insulin by the public-health department to diabetics in poor circumstances , in American cities such a provision is usual and it should be here, but up to the present it has been exceptional In the obstetrical department there was only one call for the opinion of the consulting obstetrician and none for bacteriological examination The latest puerperal pyrexia order requires a bacteriological examination of the lochia in all cases notified , but the order was born dead, for it does not say who is *responsible* for the examination, so it is always somebody else's business and is consequently left undone In 1939 the infantile mortality-rate fell to the low level of 37, which will surprise those who know Bermondsey, though the rate usually compares favourably with those of other London boroughs Bermondsey has a solarium for light treatment electrotherapy and massage In the first seven *months* of 1939 the number of persons who received treatment was 1482 and they made 30 693 attendances Unfortunately the clinic was closed in August and did not reopen until December

STIRLING

Dr D M Grant, interim medical officer of health, mentions the difficulty which may arise of obtaining sufficient supplies of insulin during the war - we hope this matter is receiving the attention it needs In September, 1939 Stirling received 2300 evacuees from the Glasgow district Of these, 827 children were examined at the

I went back again to the resuscitation ward, which was nearly full We got some more beds in, and admitted more The baby with the head wounds did not seem to be rallying A woman who had been sitting in front of her kitchen fire had been badly burnt on the face, legs and abdomen when the blast of a bomb blew the fire out into the room A young man, bending over the kettle to make some tea for his old mother had suffered a fracture of the spine when the roof fell in on him A strapping young soldier, caught in the middle of the town when the raid began, was brought in unconscious after being hit by falling masonry An old woman had several ribs cracked and a nasty shoulder wound, she died soon afterwards There were more children, crushed under falling houses Two old people who were still alive when put into the ambulance were dead when it reached hospital A couple of young Roman Catholic priests came in and flitted about the ward, doing their offices for the gravely injured and comforting the others of their flock I came to the bedside of a white-faced, motionless young woman, and felt her pulse On the other side of the ward the baby with the head wounds started to whimper protestingly under the electric warming cradle—rather a hopeful sound to the professional ear The young woman opened her eyes and said "Is my baby very badly hurt?" "He's got a nasty gash or two," I replied, "but I think he's going to be all right" A ghost of a smile passed over her face and was gone, and she closed her eyes again It was her baby, and she too had been dug out of the debris, badly crushed, an hour or two after the child She still survives, but her baby died thirty hours later

My colleague the honorary surgeon had arrived, and we went round the beds together, weaving our way in and out of the stretchers which with their occupants were now filling up a large part of the floor Such cases as were fit for operation in the course of the next hour or two could well be left to the younger men, so we made a tour of the wards As we were doing this the all-clear went, so we could use our torches a little more freely The moonlight was streaming in through gaps which had once been windows, making odd glinting patterns on the floors of the wards Outside it was a lovely night, and some imp of memory flashed on the screen of my mind the scene of Lorenzo and Jessica's love-making

Sit, Jessica Look how the floor of heaven
Is thick inlaid with patines of bright gold,
There's not the smallest orb which thou behold'st
But in his motion like an angel sings,
Still quiring to the young ey'd cherubims
Such harmony is in immortal souls,
But whilst this muddy vesture of decay
Doth grossly close it in, we cannot hear it"

We took a provisional decision on the extent to which the hospital could continue to function, and gave our instructions for the coming day's evacuation of a large proportion of our patients to hospitals elsewhere Downstairs the work still went on, and would go on well into the afternoon, before the resuscitation ward could be cleared and tidied up and made ready again for the hazards of the next night There was nothing more for us to do at the moment, and two of the ward sisters who were making a brew of tea called us in to share it They had both got up and had been busy settling their own patients to sleep in the little corridors leading to the wards, and now all was quiet We sat over sister's fire and chatted The blitz had already fallen into its place and proportion in the life of our hospital, for our recollections of the night were not only of torn and crushed bodies, of shattered wards and narrow escapes, but also of old Daddy P, who somewhere about 3 A M was found putting his thin legs out of bed "Here, Dad, where do you think you're going?" one of our party had said to him The thin legs were slowly withdrawn again under the bedclothes "I'm sorry," was the sleepy reply "I thought it was time to get up"

* * *

Your peripatetic correspondent in the R A F V R does not give the whole story Perhaps you would like to hear the other side of it My main reason for joining was that I liked aeroplanes and I wanted to fly My biggest regret in life was that I could not get parental permission to join the University Air Squadron at Cambridge Other reasons for joining were that my fiancée liked the uniform, and that I wanted to do som thing for the people whom I most admired I spe the summer at a big recruits' centre doing F F I s a inoculations and a lot of dull but essential work, a admiring the physique and spirit of the bronzed you men drilling on the promenade My only experience aviation was a pleasant two days on a high altitu course at an experimental research station There is large pressure chamber there, which holds six peop The pressure can be varied to correspond with any heig up to about 45,000 feet In it the effects of oxyg lack and "the bends" can be studied at first han

In the autumn I was posted to an operational stati somewhere in the south of England Here at last came into contact with pilots and aeroplanes a trained men It was grand to hear the booming be of a squadron of Spitfires circling the drome befo climbing away to shoot down the enemy (on one d as many as fourteen for the loss of none) Grand learn all about the planes and their achievements, climb into them, and eventually to fly in them work consists of taking sick parade of about twenty thirty men (rising to fifty or sixty in the influenza seaso who have to be sorted out, and either given sto misturæ or sent to see specialists at the nearest b hospital I wish I had the service mentality and t strength of mind to order ol ric or duty (in red ink) as oft as my senior medical officer would This said S M who takes sick parade once in six months, and sits his office writing vitriolic letters all day, becomes som thing of a public warning One has to steer the midd course between being a complete "stooge," as the R A call it, on the one hand, or becoming like him a slave the rules, refusing to see anyone except at the prop time and on the proper form, and passing one's work to other departments At the end of sick parade o sees the W A A F s, who at least give one the illusio that one is keeping in touch with female ailment After this there is an interval for a cup of tea and chat with the other M O s, the dental officer, and an officers who may have dropped in for advice Durin the morning there are "special sick"—men who hav fallen ill since getting up, or who have been injure There are "sick in billets" occasionally, and th patients in the ward to be seen Now and then the are air-raid alarms during which one has to retire to bomb-proof shelter and dressing station, and sit unde much concrete and several hot-water pipes awaitin casualties After a decent lunch interval one come back and inoculates a score of men, or examines som airmen who wish to become pilots or air gunners, who have to go overseas Occasionally one meets som interesting condition, such as Adie's syndrome and is always fascinating to detect colour-blindness b means of Ishihara's plates After tea one is more less free, unless one is orderly medical officer, when on has to stay on the camp in case of accidents Sometimes sick quarters echoes with the shout "crash on th drome!" The ambulance springs to life One leap in and is driven away furiously, usually to find a plan that has tipped up on its nose or landed with its undercarriage up, and a pilot swearing that he is unshake and does not want to be examined Occasionally on is called out at night and told to proceed to the scen of a crash, say five miles north-west of the drome Th is the most unpleasant part of one's job, searchin masses of wreckage for bodies, possibly those of peopl one has known well Fortunately it does not happe often Once weekly one does a sanitary round of th camp and makes a report In my medical education suppose I am wasting my time I prescribe stock mixtures and applications for minor complaints, bu anything serious is sent to a hospital and whirled int the maw of transference which seems to be the joy o the E M S, and contact is impossible to maintain Where now, I wonder, is that tuberculous epididymitis, that possible actinomycosis, that magnificent gumma, and that leukæmia that got better so mysteriously? I shall never know It is six months since I saw an X-ray plate, and I have forgotten what a microscope looks like Higher examinations are out of the question, but do I care? The aim of everyone in the R A F should be to keep the planes and pilots in the air, and for that end it is my privilege to work we are only able to collect 50% or 60% of the refuse f this country" This is no academic problem for the ss of kitchen waste represents potential pigs and oultry. One ton of the salvage product in Tottenham, it estimated, would feed one pig for one year and if the hole of the urban authorities collected it with equal iligence the salvage would suffice to maintain half million pigs or one-seventh of the prewar population f pigs Putting it another way we can say that such alvage is equivalent to one-sixth of the prewar importation of animal feeding stuffs Now owing to the difficulty f importing such feeding stuffs animals are being laughtered and there is already a shortage of first-class rotein

Of course it may be argued that there should be no itchen waste and the thing to do is to educate the 'openhanded British public," as Ruskin called them to ut out their kitchen waste Dr G E Friend in "The School Boy" points out that the table wastage at Christ's Hospital became vanishingly small during the ationing years 1917–19 and that by training in that school it is as low as 1% even in more prosperous times And be it remembered that puberty is a wasteful age We have, however to take things as they are, and while t may be admitted that the public as a whole. including he Services, need education in preventing wastage of food, it is none the less wrong not to put what wastage there is to the production of home grown food material.

In the same debate Lord Bledisloe expressed a fear that still further wastage of food material would result from the avowed policy of the Ministry of Food of diverting a portion of the fluid milk to the manufacture of cheese From a dietetic point of view it would be much better if the whole of the fluid milk of the country were used as fluid milk. Unfortunately the convenience of cheese and its keeping properties must weigh against its smaller food value than that of the milk from which it is manufactured. It is difficult to convey milk down a coal mine or into the fields, nor would it be easily possible to persuade miners and agricultural labourers that milk is as satisfying as cheese None the less the loss is a considerable one Most of the lactalbumin and lactose of the milk together with some protein split from the caseinogen is apt to be lost in cheese manufacture. In the past it has been largely lost by turning the whey into the sewers The effluent from cheese factories has in fact proved as detrimental to the livestock in our rivers as crude sewage, for it is an admirable pabulum for micro-organisms which rob the water of its oxygen. All this waste protein. approximately 1% of the whey, and the lactose (4%) can and should be recovered There are manufacturing plants in this country which have produced dried whey for human consumption and if in peaceful times these products made little headway it is essential that we should use them now especially in view of the lack of first-class protein in our war-time dietary All skilled manufactories find a use often a very profitable use, for their by-products

The Budget

The Chancellor of the Exchequer will open his budget on the first sitting day of the House of Commons after April 6

QUESTION TIME

Coroners and Air-raid Casualties

Major J Milner asked the Home Secretary whether he was aware that coroners' inquests were not now being held in the case of casualties apparently due to air raids, that administration of the new procedure was in the hands of mortuary attendants usually without any special qualifications or experience, and whether, having regard to the difficulties arising in regard to identification and other matters and to the possibility of deaths by violence other than by air raids being undiscovered, he would consider reversion to the system of coroners' courts with any necessary modifications —Mr Herbert Morrison replied In view of the impossibility of arranging for a coroner's inquest in every death due to war operations, a defence regulation was made at the outbreak of war which placed on the clerk of the local authority the responsibility for certifying to the registrar that death was due to war operations There is a responsibility on the local authority to see that the superintendents of mortuaries are competent persons, and unless it is clear that the death was due to war operations the case must be referred to the coroner for investigation. The question of making special provision in cases where there are difficulties of identification has recently been under the consideration of the Government, and by a new regulation which came into force on March 14 provision has been made for special inquiries by the coroner in such cases

Distribution of Medical Man-power

Mr T E. Groves asked the Minister of Health what procedure was adopted by the Central Medical War Committee and the local medical war committees in order adequately to decide the relative claims for doctors of the armed forces and civilian practice —Mr E Brown replied · The procedure adopted by these committees in selecting doctors for recruitment to the Forces provides for a full investigation in each case of the needs of civilian practice The local committee invites representations both from the doctor himself and from interested parties, such as his partners, or, if he is an assistant, his principal, a hospital or any public authority by whom he is employed, and, if he is an insurance practitioner, the insurance committee These recommendations are fully considered and if so desired are made orally If the local committee recommends recruitment, objecting parties may make representations to the central committee in the same way

Alien Doctors

Sir Henry Morris-Jones asked the Minister whether as the present arrangements for allowing alien allied doctors in this country to help in the joint cause by becoming temporarily registered medical practitioners were slow and unsatisfactory, the committee which made these recommendations would now accept, and recommend, the names sent to them by the allied government concerned in London.—Mr Brown replied The Central Medical War Committee, which acts as a clearing house for supplying alien doctors to hospitals and other authorities desiring to employ them, has received a large number of names from various sources and will, of course, be glad to receive others from the Allied Governments concerned. The procedure necessarily took some time to set in motion, including as it does the steps necessary for registration with the General Medical Council and for satisfying the general requirements relating to aliens. I am informed that it is now working smoothly

Impure Milk at Newcastle

Mr David Adams asked the Minister whether he was aware that samples of undesignated milk collected and submitted to bacteriological examination by the Newcastle upon-Tyne corporation during last month, showed satisfactory 15, unsatisfactory 14, total 29 ; and what steps were being taken to improve the quality of this class of milk supplied for food into the Newcastle area.—Mr. Brown replied I have received recent reports on samples from the corporation though I cannot identify the particular figures referred to Local investigations have been made and I understand that as a result more effective supervision is likely to be secured.

After-care of Tuberculous Patients

In answer to a question Mr Brown said According to the latest information in my possession, 121 tuberculosis authorities out of 174 in England and Wales have made aftercare arrangements. The number of new cases attending dispensaries is well maintained in urban areas, having regard to the effects of evacuation from those areas

---

Actinotherapeutic apparatus embodying some interesting new features is described by Hanovia in their catalogue The model VI (type 220) Alpine Sun lamp has a self-starting arc-tube with greater ultraviolet emission than the older standard model Constant intensity of output is maintained by rheostatic control. With this type of high-pressure mercury-arc burner a smaller tube is used, the cost of apparatus and running expenses are reduced and replacements are simplified The telescopic pillar and well-designed control unit give greater ease in the adjustment of the apparatus A new Kromayer lamp, model V, embodies improvements on earlier models. The burner starts automatically and can be operated in any position An intensity-stabiliser ensures constant output, and greater intensity of ultraviolet emission is secured by operation at higher pressure time of handing over to the receiving householders The result of inspection showed 95 to be verminous, 12 infected with scabies, 94 with septic spots, 48 with dirty bodies, 153 with dirty clothing and 310 with insufficient clothing This is an exceptionally bad consignment, but it tells us what every medical officer knows full well (and many have been far from inarticulate on the subject) that we are only at the beginning of the social reforms initiated by the medical inspection of school-children in 1907

BURY

Dr George Lobban tells us that the average annual rates, in the last five quinquennia, of deaths from pulmonary tuberculosis per 1000 population were 1 18, 0 81, 0 73, 0 59, 0 44 The rate for 1939 (0 36) was the lowest recorded The population has fallen during the past six years, from 60,100 in 1934 to 58,600 in 1939 During this period the net births were 4533 and the net deaths 5192, giving a natural decrease of 659 out of the recorded decrease of 1470 The number of cases of phthisis notified in 1939 was 31, the lowest in 25 years and little more than a quarter of the number in 1915 (120) Other tuberculosis, on the other hand, has not fallen conspicuously, for the annual average numbers notified in the five quinquennia were 26, 29, 35, 22, 23 The fall in mortality, however, was 0 31, 0 19, 0 18, 0 18, 0 13 The epidemiology of phthisis is still obscure, differing from that of other forms of tuberculosis and also from that of other respiratory infections The low phthisis rates and their rapid reduction in Lancashire are two of its most puzzling features

MACCLESFIELD

In this borough, with an estimated population of 36,350, there were 384 births in 1939 The infantile mortality was 57 2 and the stillbirth-rate 57 3, but the maternal mortality was nil Dr J H D Lawrie, medical officer of health, gives the birth-rate as 10 5, the lowest ever recorded In the four years 1936–39, the stillbirth-rates were very high 56 5, 55, 70 7, 57 3. The neonatal death-rates were also high 40 7, 43 0, 31 7, 36 4 The combined rates, which give the mortality of fœtuses carried to viability (97 2, 93, 102 4, 93 7), show a loss of potential lives of 10% which can ill be spared in a town with a low and declining birth-rate

Two analyses of swimming-bath water, one from a bath used by men, the other from a women's bath, agree in absence of *B coli* in 100 c cm but differ considerably in total counts of aerobes In the sample from the men's bath the counts were 3700 per c cm at 22° C and 4400 at 37° C, in that from the female bath, 4 at 22° C. and 3 at 37° C As *B coli* is the most resistant organism of its class, its absence ensures the absence of all intestinal bacteria capable of causing disease by ingestion The rise in the popularity of swimming raised doubt whether the benefits of the exercise might not be offset by the spread of intestinal infections through swallowing bath-water, it is satisfactory to know that this risk can be abolished We say " can be," and might add " must be," but cannot yet say that it always is

Infectious Disease in England and Wales

WEEK ENDED MARCH 22

Notifications —The following cases of infectious disease were notified during the week smallpox, 0, scarlet fever, 1205, whooping-cough, 4319, diphtheria, 1064, enteric fever, 24, measles (excluding rubella), 14,888, pneumonia (primary or influenzal), 1177, puerperal pyrexia, 123, cerebrospinal fever, 330, poliomyelitis, 8, polio-encephalitis, 0, encephalitis lethargica, 2, dysentery, 128, ophthalmia neonatorum, 83 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on March 21 was 1797, including scarlet fever 238, diphtheria, 337 measles, 428, whooping cough, 259 enteritis 26, chicken pox, 109, erysipelas, 38 mumps 1 poliomyelitis, 1 dysentery, 39, cerebrospinal fever 80, puerperal sepsis, 7, enteric fevers 2 german measles 12 glandular fever, 2, other diseases (non infectious) 88 not yet diagnosed, 110

Deaths —In 126 great towns there was no death from smallpox or enteric fever, 2 (0) from scarlet fever, 36 (2) from whooping-cough, 21 (0) from measles, 44 (4) from diphtheria, 38 (2) from diarrhœa and enteritis under 2 years, and 116 (9) from influenza The figures in parentheses are those for London itself

Liverpool reported 5 deaths from whooping cough and in the same week at Glasgow there were 14, Liverpool had 6 fatal cases of diphtheria, and Wolverhampton 4 There were 8 deaths from influenza at Bradford and 7 at Birmingham

The number of stillbirths notified during the week was 228 (corresponding to a rate of 41 per thousand total births), including 16 in London

---

Parliament

PARLIAMENT has spent a humdrum but useful week The royal assent was given to the War Damage Act which should do much to help those who have suffered through air-raids It is not often that the House of Commons goes into the division lobbies in these days of the party truce, but members did so last week on the New National Service Bill, which seeks to introduce compulsory recruitment for the civil defence services and to amend certain amendments of the National Service (Armed Forces) Act where experience has shown it to be necessary. Mr ERNEST BEVIN in moving the second reading explained that compulsion was necessary because of the shortage in certain districts of whole-time workers for civil defence But the original conception of the citizen force remains unimpaired, and has been fortified by the response of volunteers all over the country Men liable for service in the armed forces and men registered as conscientious objectors on condition that they take up civilian work under civilian control will become liable for civil defence service Women are not included in the bill It was proposed to draw mainly from men over 30 or possibly 35 years of age, and there was also a suggestion to review the cases of men who had been placed in medical grade 3 but who might be quite capable of giving civil defence service Mr C G AMMON and Mr E HARVEY paid tribute to the steps the Government had taken to protect the citizen's rights of conscience even when it believed that conscience to be mistakenly informed, but Mr MCGOVERN denounced the bill in a speech which Mr L SILKIN described as " interesting, abusive, irrelevant and muddle headed," and when the division took place 176 voted for the second reading and only 4 against Mr Maxton and Mr McGovern acted as opposition tellers

Evacuation Debts

When the Liabilities (War-Time Adjustment) Bill was read a second time in the House of Lords the Lord Chancellor explained that the shifting of the population had placed many honest people in a position of extreme financial difficulty Innocent people, such as doctors whose patients had moved elsewhere, were subject to an immediate financial strain The remedy as prescribed in the bill is to set up simple machinery to bring together the debtor and his creditors Lord SIMON said that the long-sighted creditor—to say nothing of the merciful creditor—would see the advantage of making a bargain from which he does not get twenty shillings in the pound One of the difficulties of leaving such cases to voluntary action was that a creditor who is willing to compromise may be chary of making an agreement while other creditors are free to exact the full payment The bill provides for the appointment in each district where it is deemed necessary of a liabilities-adjustment officer whose services should make it unnecessary for most cases to go to the court

Kitchen Waste

In the House of Lords on March 19 Lord DAVIES called attention to the deplorable fact that even now, after eighteen months of war, only some 40% of the kitchen waste of the urban population is salvaged and turned into feeding material for pigs Taking as a basis the results obtained by the Tottenham local authority he showed that a group of urban authorities, including Sheffield, Huddersfield, Croydon and Wembley, collected during the month of January a bare 42% of what they might have salvaged Nor did the Government spokesman deny the urgency of the problem or criticise the figures brought forward by Lord DAVIES except by putting the total possible salvage a little lower He admitted that " it must be a very bad thing at this time

THE NEUROLOGICAL APPROACH TO MENTAL DISORDER

SIR,—At first sight I doubted the necessity for discussing Group Captain Symonds's article. The fanciful picture there drawn of the medical psychologist—a designation which is not a product of this century—coupled with the devastating description of the training of the "sound psychotherapist," calls however for comment. The postgraduate teaching at the Tavistock Clinic, for which I can speak, has, however imperfectly, been evolved in order to obviate the very situation, amateur and dangerous, which Group Captain Symonds is advocating. His ominous sounding but undocumented criticisms of the results of psychological treatment mean just as much as the statements which we could all make about patients misdiagnosed and mishandled by neurologists.

Something more constructive is happening in the United States. The *American Journal of Psychiatry* of January 1941 (pp. 780–804), reports a discussion at the American Psychiatric Association, attended by the heads of the research foundations, Dr. Adolf Meyer and many others on present-day trends in neuropsychiatric research. One may perhaps usefully abstract three points from the chairman's summary of that discussion :—

5. Neuropsychiatrists need to be not only psychologically trained, but should be better oriented in the basic sciences.

6. Conversely, internists and pediatricians need a psychologic orientation.

7. In the field of psychotherapy there is need for postgraduate schools to teach and test the various psychotherapeutic methods. Such schools should be established under university ægis.

In the discussion a curriculum of three or four years was suggested for training in psychotherapy. Most psychiatrists in this country will be inclined to agree with the American opinion.

Wimpole Street, W.1. J. R. REES.

SIR,—Since Group Captain Symonds has elected to use the occasion of a presidential address, when debate is barred, for his assault on the psychological approach to mental disorders, he compels some of us to take up your valuable space. He also betrays thereby the weakness of his position, one of increasing isolation from modern medical opinion, even in his own specialty.

The spectacle of the organic neurologist, with his interest focused on the purely material substratum of nervous—not even mental—phenomena, still claiming the sole prerogative to conduct psychotherapy by the magical virtue of his "sound training" in reflex levels is almost pitiful in this year of grace. He is himself compelled to admit that human understanding and values are the keys to this branch of healing, but in the next breath denies them the right to a special discipline and method of their own. We all know how sterile the organic approach, with "bromide and a sea voyage" as the chief therapeutic standby, has been. And we can also imagine the uproar in the neurological camp if a psychotherapist had the temerity to stand up and proclaim that a knowledge "of a few fundamental principles" of anatomy of the C.N.S. and the ownership of a reflex hammer made him a competent neurologist.

As to theory, Dr. Symonds is in the position of a man trying to convince us that the quality of music will be understood by patient investigation of the physics of horse-hair scraping on cat's intestine. With this conclusion Sir Charles Sherrington, according to his latest book, appears to be in complete agreement.

London, S.W.1. H. V. DICKS.

SIR,—Several of your readers have expressed the hope that I will take formal exception to what they regard as a psychologically "reactionary" article. Although I sympathise with their indignation, I do not feel called upon to enter the jousts on their behalf. After all, Group Captain Symonds is entirely within his rights in endeavouring to describe what he calls a neurological approach to mental disorder, even if by his use of the term "mental" he cuts the ground from under his own feet. In any case it is common knowledge that whereas the stress of war usually contributes to the advancement of science it likewise calls from their sleepy Victorian hollows many a Rip Van Winkle. Nor does Dr. Symonds's brief but inglorious incursion into medical psychology call for any particular comment. This is evidently a subject concerning which he knows little and cares less. On the other hand his open incitement to the practice of psychotherapy by unqualified persons is a more serious matter. Here, to say the least of it, is an indiscretion which should not have exceeded the limits of privately expressed prejudice. Just in case any of your readers should regard his statement as authoritative I should like to draw attention to the fact that it is the fixed policy of all recognised psychological institutes to insist on increasingly stringent standards of qualification. In the case of the Institute of Psycho-analysis for example, this involves a minimum of four years' training, particulars of which can be had on application to the secretary's office.

EDWARD GLOVER,
Director, London Clinic of
Psycho-analysis.

Gloucester Place, W.1.

SIR,—In his presidential address Group Captain Symonds gave persuasive expression to a number of very controversial opinions. His views have already been challenged by several of your correspondents. Their criticisms seem to me to be, for the most part, sufficiently pertinent to allow one to hope that Dr. Symonds will think fit to reply, despite the tradition that a presidential address is immune from discussion. In this hope I venture to submit a few further questions.

Dr. Symonds says "sleep is controlled by a compact and localised mechanism in the hypothalamus. When this is disturbed sleep is disordered." Would he proceed to state that when sleep is disturbed the localised mechanism is necessarily disordered? If so how does the localisation of the mechanism affect the treatment?

Again let me submit the following typical case. A woman washes her hands twenty times a day. She consults a present-day neurologist. After careful examination he pronounces her as being "organically sound" and recommends her to seek treatment at the hands of a medical psychologist, adding—paradoxically enough—that her trouble is all due to her "nerves." The assumption is therefore justified that this particular affection of the "nerves" is beyond the frontiers of present-day neurology. I am concerned to know from Dr. Symonds:

1. Whether the neuropsychiatrist of the future will still tell the patient that it is all due to her "nerves."

2. Whether he will treat the case himself (seeing that there will be no more medical *psychologists*).

3. Whether, in that case, he will attempt to "lay bare the patient's spirit."

4. And, if so, will his chances of therapeutic success rest exclusively on his personal, apart from his professional, qualifications?

Dr. Symonds has laid us all under a debt for his brilliant and learned address. I, for one, would be further indebted to him for answers to these questions.

London, W.1. H. CRICHTON-MILLER.

SIR,—The concept of the unconscious has been accepted by most lay and medical psychologists as a valuable and even necessary hypothesis. Despite many connotations, it has played a central part in the development of modern *psychology* and psychopathology. Surely no psychiatrist nowadays questions the fact of unconscious mental life. Group Captain Symonds says that the "gap between psychology and physiology is still so wide that it is beyond imagination to pass it"; and asserts that "unconscious activity for the neurologist *means* physiological activity and no more." The neurological approach to mental disorder would seem to have *nothing* to offer the psychiatrist. What can the neurologist say of hallucinations, phantasy, dreams, memory? Are they related to "the anatomical substrata of consciousness" or are they an indication of "unconscious cerebral *function*?" And, if so, are we much further on?

We are told in this paper that some medical psychologists—the modest ones—claim that it is because of their technique that they are *successful*. If this claim could be supported, then any intelligent person, having

Letters to the Editor

FEEDING OF THE YOUNG

SIR,—That the feeding of the young is difficult under rationing no-one will deny A little calculation will show that to give them adequate amounts of first-class protein is almost impossible for the great majority of the nation Let us assume that the League of Nations figure of 60 g of total protein per day for the child of 9-10 years is reasonable Of this a definite proportion should be first-class protein Even those who deny the necessity for first-class protein in the diet of the adult admit that growing animals do better on first-class protein than on vegetable and cereal proteins I have seen young laboratory rats on casein show double the rate of growth the controls showed on the same amount and proportion of wheat gluten There are no adequate data concerning how much of the 60 g should be first-class protein I am assuming half—i e , 30 g If a child gets his full ration of meat, his aliquot share of the milk produced in the country, his ration of bacon and cheese, and in addition one egg and about 1 lb of fish per week his total first-class protein will, it is true, be over 30 g a day Thus

	(g)
2 oz *meat (taken as raw beef steak)*	11
$\frac{2}{3}$ pint milk	12
$\frac{4}{7}$ oz bacon	2 3
$\frac{1}{7}$ oz cheese	1 1
$\frac{1}{7}$ egg	1
$2\frac{2}{7}$ oz herrings	6 6
	34 0

In this calculation the figures have been weighted in favour of obtaining the requisite amount For example, if mutton chop, as purchased, is substituted for beef steak the value of the meat sinks to 4 g (with scrag end it would sink still lower wiping out the surplus and bring it to a deficit If more than $\frac{2}{3}$ pint of milk is taken someone else has to have less , there is not enough milk produced to give more We thus see that a middle-class child of 9–10 years, unless his parents go to the extravagance of more eggs, white fish, game and poultry, will only just cover the assumed need What the deficit for his older brothers and sisters will be can be imagined and we cannot offset his younger relatives against them, for their needs are proportionately greater Now if middle-class children are likely to suffer deficit, how much more will the children of the poorer classes suffer The position is more than disturbing I may, it is true, have overestimated the need for first-class protein, or imagined the middle-class folk too thrifty with eggs and fish, but that still makes one doubt whether the working classes will get enough first-class protein for their children and fear that after the war we shall meet with a lowered stature and physique of the rising generation which will take, as it did after the war of 1914–18, many years to wipe out

The remedies are free milk in the elementary schools, cheap milk for the young up to 18 years of age, and a voluntary sacrifice by the adults of their ration of first-class protein in favour of the young

A HUNDRED CASES OF BREECH PRESENTATION

SIR,—Professor Claye asks what useful purpose is served by our article on breech presentation in your issue of March 1 One obvious answer is that it was written with provocative intent to stimulate discussion of a problem on which, despite its antiquity, the last word has not been spoken In this, at least, we have succeeded Like Mr Walker we want to know, and no less than Professor Claye we deplore the sketchiness of the case-notes , but we cannot be held responsible for the sins of omission of a long series of harassed and probably overworked hospital residents No doubt they order these things better in Leeds We described case 3 as " alleged contracted pelvis " for the excellent reason that these were the actual words used in the hospital notes This paper was not based on a planned investigation, in which accurate notes would have been kept from the outset , it was written with the idea that the recording of some honest facts, representing perhaps a fair average of obstetric practice in this country, would be both salutary and instructive Many of these patients come from widely scattered country districts and the notes date back for several years It was not feasible to trace and interview all these women, nor did we feel that the omission of the unknown factors mentioned by Professor Claye altered the issue, since there was no reason to suppose that they differed materially in the two series

The treatment of 26 out of 64 cases by cæsarean section can scarcely be described as " wholesale resort to laparotomy," and the reason that the hydrocephalic was so delivered was that, regrettably enough, it was not diagnosed as such We did not state whether the classical or lower uterine segment operation was employed in any particular case because we did not consider the type of operation relevant to the issue In point of fact the classical operation was performed in every case In discussing the subject we do not pose as authorities nor do we hold any final brief for a particular method of treatment , but we are concerned with facts and not with impressions Professor Claye tells us that version at the 34th week is usually easy , it would be interesting to know, if he can tell us, what *proportion* of breeches diagnosed at the 34th week turn spontaneously if left alone He tells us that, as a result of version under anæsthesia, a certain (unspecified) number of placental separations will occur, that breech delivery per vaginam " remains the best treatment for most cases " and that cæsarean section " though technically easier kills more mothers " Without substantiation these statements are mere expressions of opinion Could not Professor Claye furnish us with the facts and figures from his own experience on which he bases these assertions ?

Dr Violet Russell has formed the impression that most practising midwives would get a fœtal mortality in breech cases much lower than 25% Until we came to examine the figures we thought our mortality was less We would emphasise, however, that our fœtal mortality figures are quite " uncorrected," and include not only stillbirths but also deaths within a few hours of delivery, whereas in many papers on the subject the fœtal mortality has been " corrected " according to the whim of the author concerned Moreover we cannot accept with complacency the " unavoidable " fœtal mortality to which Dr Russell refers

Mr James Riddell, though he gives us no figures, contributes much wise advice on how to determine the best method of treatment in any given case He does not share Dr Russell's misgivings about abdominal scars, which he thinks are to be preferred to the damage to the genital canal which may follow a difficult vaginal delivery

In his valuable letter Mr J W Burns has misinterpreted our sentence " maternal mortality in this series was nil, infant mortality 10 " This refers to the whole group of 53 hospital cases remaining after deducting the 11 cases treated successfully by version The figure 10 which should, in fact, read 9 (the error was ours) is the actual number of fœtal deaths in this group and not a percentage mortality figure In quoting our statement " if version fails then cæsarean section is the treatment *of choice*," he omits our provisos which bring our tentative opinion very nearly into line with his own views His observation on the hazards and difficulties of external version are in interesting contrast with those of Professor Claye With regard to his helpful figures on fœtal mortality in breech presentation, we should like to know if they have been in any way " corrected " , in any case it may be noted that, although Mr Burns's fœtal-mortality figure for vaginal delivery is decidedly better than ours, it is still more than double that for his own series of cases delivered by cæsarean section

In conclusion, we can assure Professor Claye that we all take a real pleasure in our obstetrics , we only wish that our experience of breech delivery gave us greater cause for pride

ALAN GAIRDNER,

Crediton

Chiseldon At the outbreak of this war he rejoined and was appointed an A.D M S

Fruity Middleton, as he was known to his friends, was an attractive and genial personality, yet when he felt a course was right he had the courage of his convictions He was well versed in the administrative problems of the army and the welfare of the soldier was safe in his hands

ARTHUR DOUGLAS WEBSTER

O B E, M D MCGILL, D SC EDIN, F R C P E

Dr Arthur Webster who died in Edinburgh on March 15 at the age of 85, was born in Nova Scotia and educated at Montreal He graduated at McGill University in 1878 and shortly afterwards went to Edinburgh where he took the Scottish conjoint qualification In 1884 he was elected a fellow of the Royal College of Physicians of Edinburgh, and four years later he obtained his B Sc in public health at Edinburgh University He practised as a physician in the city for nearly 60 years Before the last war he was medical officer of the 4th battalion Royal Scots (Queen's Edinburgh), and in 1914 he became medical officer to the 1st Edinburgh battalion (Kitchener's Army) 15th Royal Scots, and afterwards to the 16th, 17th, and 18th battalions during their mobilisation He described his experiences in "Kitchener's Army" and was awarded the O B E for his services Dr Webster's wife died eight years ago, and he is survived by two daughters and two sons, the elder of whom is Dr J Douglas Webster, director of the institute of radiotherapy at the Middlesex Hospital

Epsom College

Scholarships—The council of the college will shortly proceed to award St Anne's scholarships to girls attending Church of England schools Candidates must be fully 9 and under 16 years of age, and must be orphan daughters of medical men who have been in independent practice in England or Wales for not less than 5 years The value of each scholarship is dependent upon the means of the applicant and the locality and fees of the school selected

Pension—The conjoint committee of the college will in May award a Christie pension of £89 a year to a necessitous medical man, fully 55 years of age, who has been registered for five years, and who is in need of help

Forms of application for the scholarships and pensions can be had from the secretary's office, Epsom College, Surrey, and must be completed and returned by April 25

Sir Bernard Docker presided over the annual meeting of the British Hospitals Association on March 28, when Mr R H P Orde, who has retired after 20 years from the post of hon secretary, was elected a vice president In moving the adoption of the annual report Sir Bernard Docker explained the arrangements which had been made to ensure liaison with the Nuffield trustees in the development of the regionalisation scheme He afterwards introduced the newly appointed secretary, Mr J P Wetenhall, house governor of the West End Hospital for Nervous Diseases, to the meeting been told how, could be a successful psychotherapist It is not quite so simple as that Yet the author goes a stage further when he maintains that the sound psychotherapist in addition to having the qualities of a good doctor needs only " the aid of personal experience and a few fundamental principles to guide him " The " few fundamental principles " is the rub Even if we could define them to our own satisfaction they might well prove to be a hindrance in the hands of another Group Captain Symonds holds that the gap between neurology and psychiatry, unlike that separating psychology and physiology, is narrower than it has ever been But neurology, as here depicted, and psychiatry (including medical psychology) seem to have nothing in common Indeed the link between psychiatry and disorders of the circulatory or digestive systems is more obvious than that between psychiatry and neurology

E A Bennet

PRICE OF INSULIN PREPARATIONS

Sir,—You were good enough to publish recently a plea for the use of the stronger solutions of insulin (40 and 80 units per c cm instead of 20 units) on the ground of national economy fewer bottles would be needed, less packing and less labour Now the price of insulin has, I suppose inevitably, been raised to cover increased costs and the argument of personal economy has been added The following figures show that the retail increase is much greater in the weakest solution of insulin and that the increased price can be largely offset by changing to more concentrated insulins

Strength Units per c cm	Cost per 100 units of soluble insulin	
	Old price	New price
20	1s	1s 5d
40	11½d	1s 2d
80	11d	1s 0½d

It is clear that the increase in price can largely be avoided by using the stronger concentrations in appropriate dosage

Harley Street, W 1 R D Lawrence

DIAGNOSIS OF TUBERCULOSIS

Sir,—The letter of Dr Sinclair R Wilson in your issue of March 22 contains some statements which appear to me contrary to generally accepted opinion While all clinicians would agree that it is wrong to apply the label tuberculous without careful assessment of clinical, pathological, and radiological findings, I find it hard to believe that in army recruits the commonest cause of hæmoptysis is bronchiectasis From general experience soldiers invalided out on account of tuberculosis usually have fairly definite and in many cases extensive disease Pulmonary infarction from mitral disease presents clinical features sufficiently definite to make the diagnosis easy Idiopathic pleurisy with clear lymphocytic pleural effusion must still be regarded, in the majority of cases, as of tuberculous origin, though obviously every means such as sputum examination, culture of the fluid and serial radiography should be employed to establish the diagnosis Most clinicians will have seen many cases of frank pulmonary tuberculosis which have given a history of pleurisy with or without effusion, even when complete examination of the fluid failed to reveal tubercle bacilli Those who are meticulous enough to employ gastric lavage for the investigation of suspected cases of tuberculosis are unlikely to do so without good reason, and therefore this is not the only criterion on which the diagnosis is being based

While I am in complete agreement with Dr Wilson that the diagnosis of tuberculosis should not be made on insufficient grounds, it is surely a dangerous practice to relegate tuberculosis to third place in the causation of hæmoptysis in young army recruits

County Sanatorium, Harefield, Mdx John C Roberts

DEDUCT MISFITS AT SOURCE

Sir,—One of the most popular ways of wasting public money at present is for medical boards to pass into the Army men with definite disabilities, physical or mental I do not suggest that the boards are either careless or incompetent Evidently they have neither the time nor the facilities for the full investigations necessary to prevent these mistakes Yet the investigations hav to be made sooner or later Often it is later, after muc money has been spent in equipping the man, attemptin to train him, or find some work that he is fit for, sending him to this and that hospital or specialist (a the cost of untold " ambulance-miles ") Finally va quantities of paper and time are expended by all sorts people, important and otherwise, in getting him di charged Is it worth it ?

Granted that the present boards have a lot of men examine in a limited time, but why not have mo boards ? It will be objected that there are not enoug doctors But there are—hundreds They wear expe sive uniforms and sit at wooden tables trying to cope wit the chronics which have been missed by the board Let us have more civilian boards with plenty of time consider each case They need not be large, or compose of highly experienced practitioners, but they shou have the best possible facilities for obtaining specialist opinions Given clear instructions as to what is expecte of them, even the least experienced doctors are capab of passing the obviously fit men and referring the doub fuls to their more senior colleagues Surely this woul be more economical than the present system, thoug perhaps less impressive as regards the rate of intake in the Army

Brancepeth, co Durham W E Hick

TOXICITY OF SULPHATHIAZOLE

Sir,—It was with considerable interest that I rea your annotation of Jan 11 (p 49) concerning the invest gations of S Moeschlin and H Hurschler (*Schweiz me Wschr* Oct 12, 1940, p 972) These workers report the presence of toxic granules in red blood-cells of subjec getting sulphonamides other than sulphathiazole O the basis of these findings it was thought that sulph thiazole was probably less toxic to red blood-cell although the reason for this remained unexplained

Recent studies by our committee for the study pneumonia at the Philadelphia General Hospital (s Reinhold, J G, Schwartz, L, Flippin, H F an Bethlahmy, S *Proc Soc exp Biol, N Y* 1940, 45, 31 furnish a logical explanation for this finding Thu whereas sulphanilamide and to a lesser extent sulph pyridine penetrate red cells readily, this is not the ca with sulphathiazole We have found that sulph thiazole shows a marked disproportion between concentr tions in cells and plasma when analysed by the metho of Bratton and Marshall In 13 convalescent patien the mean ratio of whole blood free sulphathiazole serum free sulphathiazole was 0 74 ± 0 09 standa deviation Ten patients treated with sulphapyridi showed a ratio of 0 89 ± 0 07 This difference betwe the drugs is highly significant When the concentratio of sulphathiazole in the blood-cells was calculated, t ratio to the concentration in blood plasma w 0 437 ± 0 19 as compared with 0 645 ± 0 18 f sulphapyridine likewise a significant difference

Philadelphia General Hospital Leon Schwartz

WOUNDS OF THE KNEE-JOINT*

By W. H Ogilvie M Ch Oxfd, F R C S

COLONEL, A.M.S ; SURGEON TO GUY'S HOSPITAL

The last war saw the re-establishment of the simple outlook on infection and wound healing that had been taught by Hunter and Lister, but obscured by later discoveries The outlook remains unchallenged, but the actual methods of 1918 are not necessarily applicable to the changed conditions, both of war and of surgery, that are met today Then nearly all wounds were caused by fragments of high explosive in exhausted and mud soaked men, now they are inflicted by many different weapons often under almost sterile conditions Then early excision was the only sure safeguard against infection or gangrene, but new therapeutic agents have since appeared—particularly improved sera, the sulphonamide drugs and preserved blood and plasma—that can help the resistance of the tissues so powerfully that less drastic surgery is often possible Then casualty clearing stations had all the refinements and immobility of a civil hospital, today the aeroplane prohibits elaboration in front-line units, and discourages the use of methods that demand a large staff and constant supervision, or whose success would be jeopardised by sudden evacuation Thus the surgery of this war promises to be more complex and yet more simple than that of the last, there will be more therapeutic alternatives more conservative operations and fewer destructive ones, but all methods must be straightforward and foolproof

Where wounds of joints differ from those of non-articular parts of the skeleton they differ for the worse A joint is a cavity of complex shape lined by structures whose resistance to infection is below the average. It cannot be laid widely open for surgical toilet without destroying its mechanism, it cannot be cleansed and washed out easily, and it cannot be drained efficiently If infected it becomes a deep pocket from which toxic absorption takes place readily and from which pus tracks along tissue planes when the capsule is ruptured In the middle of a limb nerves are scattered and there are alternative blood channels; round a joint nerves and vessels are bundled together and often destroyed by the missile that wounds the joint. A bone will function as long as it has continuity, and if the ends are in their correct relationship it will work well however bizarre its shape may be between, but a small amount of damage will render a joint useless Moreover, a bad joint is worse than no joint in other words, pain and instability are worse than ankylosis

The knee is the largest articulation and therefore gives most opportunities for conservative and reconstructive surgery While important structures are grouped round other joints in the knee they are all placed behind, so that uncomplicated articular injuries are more common; on the other hand, its size renders any infection particularly dangerous The synovial membrane lining the knee-joint is very extensive It resists infection poorly, but it has antibacterial powers, and can also form adhesions and limit sepsis to part of the cavity The main compartments are the subcrureal pouch above and in front, and the two condylar pouches behind; the ligamenta alaria seal the first from the second two, the cruciate ligaments and the ligamentum mucosum the two posterior pockets from each other These folds when inflamed can limit the spread of infection, unless movement or tension force their barriers Immobilisation of an injury of the knee, from the earliest moment until infection has been averted or overcome is therefore the key to success

In a forward area, local treatment is limited to cleansing the skin applying an abundant sterile dressing and immobilising the limb for transport The Thomas is the best primary splint, but Cramer's wire or a wooden splint may be applied or the legs may be tied together Any form of immobilisation is better than none The first dose of a prophylactic course of sulphanilamide, three tablets crushed and taken with a drink of hot lemonade, should be given if possible and the amount and time noted on the card

WOUNDS SEEN WITHIN SIX HOURS

At the casualty clearing station or the first operating centre reached every wound of the knee-joint must be regarded as an urgent case for examination and probable operation The most important group will be those seen within the "pre-infective" or "grace" period of six hours Such cases may be roughly divided into (1) those without bone injury, (2) those with injury to the patella only or partial injury of femur or tibia; and (3) those with complete fracture of femur or tibia or complicated by vascular injury In the first group, through and through bullet wounds with punctured entry and exit holes do not usually require operation; wounds with low-velocity projectiles often come in the same category At times of stress these can be evacuated further temporary immobilisation being replaced by something efficient, and the course of sulphanilamide continued If however they can be retained they must be watched carefully, the joint must be aspirated if it gets at all tense, and immobilisation must be continued till infection is clinically overcome The early movement of injured joints is as unsound as the early movement of fractures Movement will be regained more certainly if we aim at preserving the apparatus of movement that is the integrity of the joint than if we practise the desired movements before the joint has settled down. Where evacuation is a pressing need it must be remembered that bullet wounds are always less serious than shell wounds of a similar nature and that an open wound of a joint with escaping synovial fluid is less likely to go wrong if properly immobilised than a valvular wound or a damaged joint distended with fluid or blood

Apart from the group that are left alone for preference and those that are left under stress, the majority of penetrating wounds of the knee-joint of the first class, and all those of the second class with injury to the patella or partial injury to the other bones, should be operated on Before operation every case must be radiographed to detect and localise foreign bodies and to determine the amount of bone damage During the period of investigation and preoperative skin preparation the limb should be moved as little as possible Operation should be done under a tourniquet with the strictest aseptic precautions The wound track, if a simple one, is excised in one piece down to and including the hole in the synovial membrane Where conditions permit, it is well to change instruments at this stage The joint is then opened along anatomical planes sufficiently to allow inspection and cleansing of its interior Foreign bodies are picked out The cavity is irrigated thoroughly with 1/1000 flavine, which will remove the blood clot and will often wash out bits of cloth or fragments of metal Local injuries to bone are treated as radically as possible A patella splintered by a projectile should usually be removed completely Holes in the femoral condyles or the articular surface of the tibia may be scraped with a curette or trimmed with a small gouge till they are smooth cavities lined with apparently healthy bone It was a common practice in the last war to dry such cavities with spirit and rub them lightly with bipp Today the place of bipp would be taken by powdered sulphanilamide, dry or mixed in a paste with Vaseline, and such a practice is thoroughly sound

After excision the difficult question of subsequent treatment must be decided Up to the present our experience and that of the French has been that primary suture even under the most favourable conditions of wound patient surgeon and hospital, is a risky experiment one that has more often been disastrous than successful In the knee, however suture, or at any rate partial suture, should be tried if at all possible, for a

Care of Cripples

Speaking at the annual general meeting of the Central Council for the Care of Cripples, Mr Ernest Brown, Minister of Health, said that the Government had accepted responsibility for looking after people injured by enemy action, or in the course of their military or civil defence services But he relied upon the council to see to it that we were not allowed to forget or neglect the ordinary " civilian " cripple Under the Emergency Hospital Scheme 19 orthopædic centres had been established in England and Wales, to which the majority of serious fracture cases, whether military or civilian, were transferred At each of these centres there were skilled and experienced surgical staff—in one centre there was an American team and a physiotherapy department with trained masseuses Facilities for physical training, games and occupational therapy were also being developed, and other hospitals are being brought into the scheme

Mr Brown asked what would be the effect of this scheme on the care of cripples after the war ? Some of these special hospitals would disappear as the buildings in which they were housed returned to their normal uses, but some of them would make a permanent addition to the country's orthopædic services The new hutment hospitals were not a collection of the old army huts, doomed to dilapidation They were soundly constructed pavilions, built often in brick and concrete, and designed to endure for many years, full of light and air

The meeting was presided over by Sir Geoffrey Peto, who said there must be a water tight scheme for the continuous and expert treatment of every war disabled casualty from the day of injury till his restoration to the Forces or to industry This involved seven Government departments and was far from complete, but great progress had been made lately

War-time Standards

On the outbreak of war the British Standards Institution realised that its peace-time procedure was inadequate to deal effectively with the new demands A number of small executive committees were therefore set up for the various sections of its work, who were made fully responsible for the preparation of any war emergency specifications They were given authority to restrict the usual wide consultation of industry to those interests directly concerned, and the reduction of the time usually given for comment on draft standards Any British standards issued under war time procedure will of course be reviewed directly peace comes again Government departments are employing the institution's machinery for the preparation of war emergency specifications The institution is invited to send a representative to appropriate meetings of the materials committee of the Production Executive, which is representative of all Government departments The first issue of the war emergency specifications for tins and cans for food products and other commodities is estimated to have saved 40,000 tons of steel in the first year The institution has also provided the Government, in connexion with the Purchase Tax, with definitions which give the dividing line between babies', children's, and adults' clothing

Lieutenant J M Muir, M B Edin , R A M C , has been awarded the D S O for gallant and distinguished services in the field at Sidi Barrani

The following awards have been made in recognition of distinguished services in the Middle East from August to November last year —

O B E (military division) —Major (temporary Lieut Colonel) A O Bekenn, M R C S , R A M C , Major Devendra Nath Chakravarti M B Lucknow, I M S , Major (temporary Lieut Colonel) J M Macfie M C M B Glasg , R A M C Lieut Colonel James Melvin, M C M B Aberd , R A M C , Lieut Colonel (temporary Colonel) F G A Smyth, M B Lond , R A M C and Lieut Colonel (temporary Colonel) Q V B Wallace M C , M B Dubl , R A M C

M B E (military division) —Lieutenant H R, Hartnell, M R C S , *R A M C , and Lieutenant (acting Captain) Gerard Loriman,* M B Durh , R A M C

On April 13, at 6 45 P M , Mr Walter Deacon, president of the Pharmaceutical Society, which is celebrating its centenary, will give a talk in the home service on One hundred years of Pharmacy

Since publication of the last list of subscriptions to the Medical War Relief Fund over £900 has been received, bringing the total to over £20,000

A meeting of the North Western Tuberculosis Society will be held at the Tuberculosis Offices, 352, Oxford Road, Manchester, on Thursday, May 8, at 3 P M , when Dr S Vere Pearson will speak on What are we aiming at in Collapse Therapy ?

Notes, Comments and Abstracts

TO HOSPITAL BY AIR

SWEDEN has a service of air ambulances which fly to the help of sick people in remote districts whence other means of transport are slow and exhausting In the past those living in such regions had to travel by Lapp sledge or boat and sometimes took several days to arrive at the nearest hospital—often too late for their lives to be saved Surgeon-General Fritz Bauer reports[1] that there are now four aircraft in the ambulance service, operating from Stockholm, Ostersund and Boden Three are single-engine Junkers, the fourth a double engine Beechcraft In addition to the pilot and mechanic (who are members of the Swedish air force) each plane can carry two stretcher patients and has seating accommodation for two more people Wheeled landing carriages, pontoons or skis can be fitted to the aircraft as required No aerodromes await them in the lonely mountainous regions to which they penetrate, in summer they alight upon lakes, in winter on the snow fields The first Swedish ambulance plane was bought in 1924 at the suggestion of Prince Charles, funds being provided by the Swedish Red Cross and the State Since 1932 the service has been maintained entirely by the State Experience shows that patients stand the journey well, and that most disorders can bear the light strain of flying in modern aircraft Up to August, 1940, some 1700 people had benefited by the service , accidents have been few There are now hopes of providing helicopters or autogyros adapted for stretcher cases , these of course would greatly simplify the problem of landing The Swedish Red Cross and the government are persuading owners of private aircraft to adapt their machines to carry stretchers , subsidies will be given for this purpose provided that the machines are placed at the disposal of the nation in times of war A committee set up by the Royal Aero-Club (K S A K) suggests that an international agreement would be welcome whereby builders of transport aeroplanes would be obliged to equip them to carry stretchers International agreement on this or any other point would indeed be welcome

A HOSPITAL GUIDE TO THE PURCHASE TAX

Mr W E C Baynes, barrister-at-law of the Inner Temple, has codified the purchase tax for the hospital administrator in a leaflet of four pages[2] He sets out briefly the six general principles governing the application of the tax, lists the goods likely to be needed by a hospital which are subject to the tax or exempt from it, and even finds room for an appendix giving the simple drugs and simple chemical compounds which go free No relaxation of the act is made for hospitals or other charitable institutions, though many of their needs are included in the list of exemptions, and where a hospital obtains goods from the wholesaler at a cheap rate the tax will often have to be paid on the higher rate which would be charged to the ordinary purchaser An exception to this will be goods which are put up in special packs exclusively for hospitals Surgical requirements are not subject to the tax, but some of them crop up unexpectedly under other headings—thus tax will have to be paid on india-rubber gloves along with every other kind from fur-lined to fabric, and bandages if they are not made up will, as textiles, have to pay the full 33⅓%

Mrs Clerke Brown of Hestor's Cottage, Kingston Blount, near Oxford, whose son 2nd Lieutenant Charles Clerke Brown was reported missing in June 1940, and later killed, is anxious to get in touch with the relatives of any British doctor who was at the Hôpital Riband, St Omer, last June

The Society of *Chemical Industry will hold the* third of its discussion meetings on the nation's food at B M A House, Tavistock Square, London, W C 1, at 11 A M on Wednesday, April 9, when the subject will be vegetables as food

Six lectures on industrial medicine for medical officers appointed to factories will be held in the medical school of the University of Birmingham on April 19 and 20 Further particulars may be had from the dean of the faculty of medicine, The Medical School, Birmingham 15 int that danger lies The anterior compartment should e opened by two parallel incisions starting opposite e midpoint of the patella on each side and ¾ in away om it, and extending to the top of the subcrureal ouch, whose extent is determined with a finger The ondylar pouches may be opened as well, by cutting on e point of a pair of hæmostats passed back into them rough the lateral incisions , these openings are necesrily too small to drain freely, but they are advisable severe infections In the last war it was common ractice, after opening the joint, to pass rubber tubes own to the opening in the synovial membrane but not to the cavity, and to rest the limb in a Thomas splint ung from a balkan frame, with an extension of 8–10 pulling through strapping or glue on the leg The odern practice of packing the drainage incisions with aseline gauze and immobilising the whole limb in a losed plaster hip spica including the foot and the elvis appears to be sounder The aim of extension as to overcome spasm of the muscles, give rest to the mb and prevent pressure necrosis of the articular artilages But the rest provided by suspension with xtension is that of two cancelled forces and not the omplete immobility imposed by a plaster case The eight removes the pressure from the cartilages, but in oing so tends to open the joint, preventing localisation f the infection and encouraging its spread to the condylar pouches In any case the battle for a septic nee-joint is virtually decided in 4 days—if the infection s overcome within that period, the joint is saved before he cartilage has had time to suffer , if it is not, joint and artilage are lost together

[2] Central Bureau of Hospital Information Memorandum No 158 Obtainable from the director of the bureau, 12, Grosvenor Crescent, London, S W 1 3½d post free

After drainage and fixation, the patient must be watched anxiously His general condition and his own estimate of the progress of the leg are the only reliable guides If all goes well, the plaster case should be left undisturbed for a minimum period of 3 weeks , if the patient is not better at the end of 4 days, it is usually better to amputate the leg The great danger in septic knee-joints is to hang on too long Most surgeons with experience of the last war would agree that, with this particular injury, there were more lives lost unnecessarily by late amputation than limbs lost unnecessarily by too early amputation In amputating for sepsis in a patient who is gravely ill, the guiding principles are to do as simple and rapid an operation as possible, to leave the divided tissues widely open, and to arrange things so that the permanent stump which will be obtained by a secondary operation later in a clean field can be made as long as possible Disarticulation at the knee with a long anterior flap consisting of skin only is the simplest method, but it leaves a vascular bundle practically unprotected by muscles at the most posterior part of the stump, and in these septic cases is very prone to be followed by secondary hæmorrhage Amputation through the femur just above the condyles, with a long anterior and short posterior flap, is better The flaps should be approximated by two or three stitches over wide slabs of vaseline gauze covering the divided bone and muscles

Infected wounds of the knee-joint were responsible in the last war for a high proportion of fatalities at base hospitals, and it is not surprising that a number of alternative methods for dealing with them were evolved Willems claimed good results by encouraging active movements from the time of drainage , the method is in direct opposition to the basic principle of surgery that injured and infected tissues require rest, and it failed singularly in the hands of other surgeons Jaboulay's plan of postural drainage aimed at making the suprapatellar pouch, opened in the usual manner, the most dependent part of the joint, thus preventing the pus from distending the condylar pouches, where it is very apt to burst into the popliteal space and track into the calf or thigh along the vascular sheaths This was attained by nursing the patient on his face, or with the limb projecting vertically from the bed It is difficult to nurse a patient who is gravely ill and wounded elsewhere in the prone position without moving his septic joint , with a plaster spica the difficulties are less, and the device may often prove useful The vertical position of the limb is most uncomfortable, and involves some degree of circulatory deficiency in the foot Open arthrotomy was tried extensively during the middle period of the war Using a horseshoe incision, like that for a classical excision of the joint, the patella was thrown upwards, and the whole joint laid widely open by dividing the cruciate and lateral ligaments and splinting it in a position of flexion It was hoped that with unrestricted drainage infection would be overcome rapidly, and that a useful stiff leg could then be secured by excision In practice the dressing of these large sensitive surfaces proved very exhausting to the patient, and a state sufficiently clean to justify excision was seldom reached , the majority went on to amputation after about a week Irrigation with Carrel tubes had many advocates, but did not give results comparable to those now obtained by packing the incisions with vaseline gauze and immobilising the limb in plaster The Carrel method is too elaborate for use in military surgery under the conditions prevailing at present , it does not wash out a complicated cavity like the knee-joint, but rather tends to set up eddies that carry infection to fresh recesses, distend the posterior part of the capsule and lead to sinus formation

CLOSED PLASTER

Closed plaster is firmly established as the best method of treating the majority of wounds of the limbs under the circumstances of the present war, but it must confer real immobility or it is worse than useless The surgeon who assumes responsibility for the welfare of his patient must also be responsible for the plaster case that is applied afterwards, though he may not always be able to make it himself Many bad plasters are put on, not through ignorance but because the surgical teams are so hard pressed in coping with the wounded awaiting attention that they cannot give the time necessary for good plaster work A second team, trained by the surgeon, working in tandem with him, and showing him their cases at the end of an operating spell is a satisfactory solution The one-piece plaster case, described by Trueta, made from layers of material cut to pattern and soaked in plaster cream, promises to simplify the application of good casts, for the materials can be brought to the side of the table on a special trolley by a trained sister, and the application is then a matter of minutes only

A good case must immobilise well enough, far enough and long enough It can immobilise well only if it is skin tight over the greater part, with no more padding than a little thin felt over the vulnerable bony points, particularly the acromion,' the anterior superior iliac spines and the sacrum Bony points that were formerly considered to be in need of protection, such as the malleoli, remain comfortable if the cast is moulded round them so closely that no movement takes place between them and the plaster A case must extend far enough to include the joint above and below the injured one A plaster for the ankle must include the knee, for the knee a hip spica is required To immobilise the hip-joint a double hip spica is essential, but it need not extend above the iliac crests , the long Witman plaster extending to the nipples is based on the erroneous assumption that the spinal column can be used, like the stick in the toffee apple, to immobilise the pelvis A plaster for the wrist must go well above the elbow, and one for the elbow or shoulder must include the trunk on a shoulder spica The case must immobilise the joint uninterruptedly *for at least 3 weeks*—the shortest time in which it can be assumed that an infective process is overcome and not merely localised Failure to ensure this is a frequent cause of failure in the surgery of infected joint wounds, for even the slight movement that is unavoidable in changing a plaster may lead to a flare-up of an infection that was walled off, and to the destruction of a joint that might have recovered with movement Changes of plaster are usually undertaken, not because the patient is ill or uncomfortable, but because the discharge has become offensive or has softened one segment of the plaster and destroyed immobilisation A good dressing of fluffed gauze should therefore be applied over the vaseline packs, covered by one or two layers of wool firmly bandaged, and the case should be so constructed that its strongest strut is well away from the wound These measures will protect the plaster, and, if the rest of the case is unpadded, will not interfere with immobilisation drained knee nearly always means limited movement and often complete stiffness afterwards. Where a knee wound in a fit patient is received by the surgeon within 6 hours and is treated by thorough debridement including the removal of all foreign bodies, the synovial cavity at least should be closed by interrupted sutures of the finest catgut. In closing it, any bone lesion should if possible be exteriorised by mobilising or turning down flaps of synovial membrane; owing to the size and mobility of the subcrureal pouch this is often possible with partial lesions of the femoral condyles. Some writers advise that the capsule should be closed as well, but this step is not without risk, since suture of a defect in such a tough structure leads to tension which is inimical to clean healing. The skin may be closed with interrupted sutures in a favourable case, but if there is any doubt it is better to pack the outer layers of the wound with vaseline gauze down to the synovial membrane, rather than to risk a subcutaneous infection which will later invade the joint. After a well-planned and well-executed operation, well-planned and well-executed immobilisation is equally important, and careful supervision even more so. The only apparatus that gives 100% immobilisation of the knee is a plaster spica, and it is therefore better to use this method than to retain the advantages of inspection and extension that a Thomas splint allows. Sulphanilamide should be given for a full 4 days in every case. The progress is judged by the condition of the patient, his chart and the comfort of his leg, and the dressings are left alone for at least 10 days. If evacuation is imperative before this time, no joint wound should be allowed to travel with sutured skin. Whatever grounds there may be for optimism the surface stitches should be removed and the skin wound packed lightly open before the patient is allowed to leave.

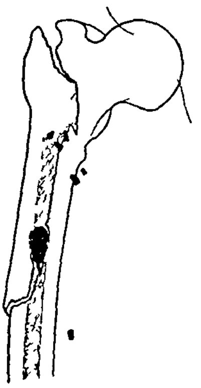

FIG 1.—Sketch of radiogram showing bullet and splinters. These were not removed and did not interfere with union. Some of the fragments emerged through the perinæum.

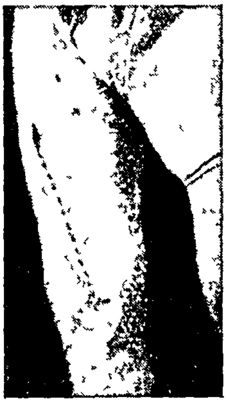

FIG 2.—Limb after removal of plaster. Ink line marks route of bullet. Six months after the injury there was full extension of the knee joint and flexion to a right angle.

Of the third class, wounds with complete fracture of the tibia or femur, little need be said. Such wounds are often complicated by injury to vessels or nerves and demand primary amputation. Where there is no such injury, a debridement as thorough as possible should be done under a tourniquet. The synovial membrane should again be closed as completely as the defect will allow, but further suture is unwise. The wounds are therefore packed with vaseline gauze, and the limb immobilised in a plaster spica. An injury to the head of the tibia is usually more serious than one to the femoral condyles; the bone lesion cannot be excluded from the synovial cavity as can one in the femur, it can less often be excluded from the surface, and the softer cancellous bone is more liable to infection.

WOUNDS SEEN LATER

Wounds of the knee-joint received between 6 and 24 hours after infliction require anxious consideration. Some will be clean enough for debridement, as judged by the appearance of the wound and its surroundings, the condition of the patient, his temperature and pulse, and possibly the kind of fluid that flows or is aspirated from his joint; but at this period the skin should not be sutured. Others will be frankly infected. In between will be cases where the wound is a little angry but the joint is not really septic, where drainage must be established and foreign bodies removed. In these, limited debridement designed to cleanse the track and remove foreign bodies and loose bone fragments should be done, but it is necessary to work cautiously, incising undamaged tissue as little as possible and keeping the dissection to the already damaged zone. The joint should be washed out with weak flavine solution and afterwards the whole track should be packed with vaseline gauze, the synovial hole being left open or closed in part. The limb is immobilised as before in a plaster spica, and the patient put on a course of sulphanilamide.

After 24 hours the bacteria have established their entry and the tissues have established their defences. The time for debridement is past, and the alternatives are expectancy or drainage. The decision will above all depend on whether infection is being overcome or is likely to be overcome, or whether it is getting the upper hand, in short whether the patient is doing well or doing badly. Many cases which, had they arrived earlier would undoubtedly have been taken to the theatre, now appear to have combated their infection. Among such may even be wounds where the projectile is still in the body but out of the joint.

A soldier, wounded at Dunkirk, reached hospital in England five days later with an entry wound on the inner side of the right knee, and synovial fluid pouring out. The bullet had passed up, struck and fractured the femur and was lying in pieces all round the upper part of the thigh (figs 1 and 2); no attempt was made to remove any of the fragments. With drainage and plaster and a course of sulphanilamide he recovered with nearly full knee movement.

A fit patient, good immobilisation, smooth transport and prophylactic chemotherapy may all have contributed to the result. Here the wise policy is to continue immobilisation and sulphanilamide, watch carefully the condition of the patient and the wound, aspirate the joint if need be, be ready to drain or to cut down on a foreign body—in short to pray for the best and watch for the worst.

SEPSIS

As in all wounds, the first and most important indications of infection are to be found in the general condition of the patient, his temperature, his pulse and his appearance. A man with a wound of the knee-joint that is doing well looks well and feels well. If the wound is becoming infected he begins to look ill, and an experienced ward-sister will often notice the change before the patient or the doctor. Pain is the most important single symptom; a joint that is painful is an indication for alarm. Examination of the dressing will tell us more, and the indications of mischief are in the surroundings rather than in the wound itself. If the surrounding skin is soft and cool and the joint is not tender, there is little cause for alarm whatever the appearance of the wound itself. Redness, heat, œdema and tenderness of the skin over the joint and pain when the patella is moved sideways indicate infection. Aspiration will usually be performed to aid the decision, for a recently injured joint, whether infected or not, always contains fluid. Clear or opalescent fluid indicates a healthy reaction, turbid or purulent fluid a failure to react. Some blood is to be expected and has no significance, but hæmolysed blood is of grave import since it betokens a streptococcal infection. A moderate number of mononuclear cells indicates no more than a healthy reaction; but polymorphs suggest that infection is getting the upper hand. Organisms can be identified from the fluid in a few hours. *Clostridium welchii* is the least serious if the infection is purely articular. A staphylococcal infection is grave, but will usually yield to energetic treatment. Infection with a hæmolytic streptococcus is the most dangerous.

As soon as infection has been recognised, the knee should be drained, for it is in the infected but undrained important group and in times of war other cases be expected , Lhermitte (1918) reported four cases trauma with narcolepsy the main symptom The reported by Souques (1918) had narcolepsy with uria, and a case of Haenel (1929) had narcolepsy, plexy and mental changes Daniels (1932) Singer 7), Pollock (1930), Kahler (1921) and Redlich (1917) also reported cases In Adie's first group of 20 s, trauma is not mentioned as a possible ætiological or, although in 2 of the cases an accident had been erienced , one had a minor blow on the head at age of d the other, a man of 48, had symptoms following a on the head with an umbrella Of Kinnier Wilson's ses 1 gave a history of an accident to the head with re concussion two years before the symptoms began

ase 2 —A girl of 14 In June 1937, a heavy piece of lead rom a skylight on to the top of her head She was dazed, continued work all day despite severe headache She did vomit and had no diplopia Next day she returned to k, but fell off her bicycle and she was sent home She was ork for several weeks with severe headache and was very able In November, 1937, she developed attacks of kness of the legs occurring without warning and causing to fall , she was able to get up at once These occurred e or four times a week In June, 1939, she was admitted ospital , no evidence of gross pathology was found on full rological and X-ray examination Two years after the dent she developed attacks of irresistible sleep, coming on ny time, even when eating and occurring several times a They only lasted a few minutes and the sleep was ays dreamless , her sleep at night was normal, but usually urbed by dreams A year after the accident she had eloped an excessive appetite, and polydipsia, but states re was no polyuria Menstruation, regular before the ident, has been irregular ever since Until the accident, was happy, lively, and rather a tomboy type , afterwards was irritable, less sociable, morose, aloof, restless, lacked husiasm and had constant headaches In April, 1940, at age of 17 she married, but minor symptoms persist and is irritable with her husband

This case was seen by Mr Harvey Jackson who nfirmed a lesion in the hypothalamic region It illus- tes many of the symptoms of a third ventricular ndrome—narcolepsy, cataplexy, menstrual irregularity d polydipsia, bulimia and personality changes There no increase of weight, no diplopia, no polyuria provement has been steady , narcoleptic attacks have t been present for some months and the cataplectic tacks have also disappeared She is still altered in rsonality and her menstruation is irregular

Case 3 —A girl of 16, an electrical tester In January, 37, a 2 lb insulator fell on her head over the frontal region e was severely dazed and vomited , she was taken home d immediately fell asleep, being difficult to rouse after some urs Next morning she returned to work, but has no mory of this, and was sent home by the management as e was obviously unfit The headache persisted and she was oubled by diplopia, pains in the left ear and the left side of e face She remained in bed 14 weeks, being treated for ncussion During this time she had attacks of uncontrol ble drowsiness In her sleep she would snore loudly, a thing e had not done before, but she was not always unconscious, nce she could often hear but could not answer Perhaps the ore was an attempt to articulate On getting up, she ould have attacks of sleep in the cinema, during meals, when ading and even on holiday at Blackpool In some of the ttacks she would talk a lot and sing, and was very difficult rouse even for meals Two weeks after the accident, after eavy vomiting, she had two "fits" on one day, in which she as rigid all over, did not bite her tongue and had no enuresis hese attacks continued daily for a time There was no aura eakness of the legs was also noticed , she would fall about nd had difficulty in getting up These attacks were not nduced by any emotional disturbance, but "if I laughed I ecame sleepy again" Excessive appetite was noticed, but here was no polydipsia, nor polyuria nor menstrual changes n October, 1937, she was admitted to hospital for a month he had no fits during this time and only one attack of hyper omnia The cerebrospinal fluid pressure was raised to 200 mm The optic discs showed a pathological congestion with a uggestion of a recent retrobulbar neuritis, the edges being hazy and there was slight diminution in the fields of vision Otherwise, no abnormal neurological or radiological signs were apparent After discharge from hospital the sleep attacks continued and falls were frequent "My knees would suddenly give way" In May, 1939, she was admitted to the National Hospital, Queen Square The visual defect was then considered to be hysterical and was improved slightly by faradism and suggestion She had no sleep attacks Before the accident she was a well nourished, happy and pleasant girl , since she has been cross and irritable and has lost 14 lb in weight She is improving slowly, but is still easily tired, with giddiness, headache and pain of the left side of the face for which the dental surgeon can find no cause Her father died of an inoperable temporosphenoidal glioma

In this case the cataplexy was independent of emotion, but laughter would cause drowsiness There are symptoms, however which suggest an hysterical overlay, notably the loud singing in her sleep , this symptom is also recorded by Singer (1917) in a case of traumatic narcolepsy The so-called "fits" may also have been hysterical , they were never seen by a doctor The narcolepsy attacks, the cataplectic weakness of the legs, the diplopia, the raised C S F pressure, however, are beyond dispute There must therefore be some organic lesion from the original contusion

Case 4 —A district nurse When nursing a patient on Sept 15, 1939, she hit the right parietal region of her head violently against an oak beam She was momentarily dazed, but entered her car and drove away , after a short distance she suddenly vomited and had severe headache and double vision These symptoms continued and on Sept 17 she became unconscious and was afterwards kept in bed for a week , on getting up she felt as if she "had no legs" and could hardly stand up or walk At Christmas she began to suffer from attacks of uncontrollable sleep which she tried to resist , the effort made her irritable and her legs gave way and she fell to the ground The sleep attacks were dreamless, did not interfere with her normal sleep at night, and sometimes came on within an hour after getting up in the morning She was not always unconscious, but had a feeling that her mind marked time and continued to think about the last idea in her mind before the attack The cataplectic attacks coincided with the narcolepsy , she remembers the first attack as associated with "an inability to breathe and a feeling that someone had hit me behind the knees causing the legs to give way" The right arm and hand were also involved in these attacks, a sudden loss of grip causing her to drop articles Early in 1940 the sleep attacks became less frequent, although yawning remained a regular symptom , if she got the desire to sleep she found it better to submit, because resistance caused irritability and foul temper The cataplectic attacks still continue and come on if she tries to overcome the defective vision or to concentrate on mental problems On examination a slight lateral nystagmus was found, but no changes in the optic discs , slight diminution of the field of vision on the right side and diplopia on looking upwards and to the right No other clinical signs were found, but the skull was not radiographed or the C S F tested This case was seen also by Mr Harvey Jackson who suggested that the symptoms were due to a lesion, probably in the form of minute hæmorrhages, near or in the third ventricle There was no bulimia, polyuria or increase of weight She dared not drive her car because it induced sleep

DISCUSSION

In most cases of narcolepsy there is no history of preceding illness, no indication of tumour, as a rule no signs on full neurological examination, and the cerebrospinal fluid is usually normal Cases of this type may be called idiopathic , but I am inclined to agree with Daniels (1934) that they probably owe their origin to an attenuated strain of the virus of encephalitis, not virulent enough to cause the defined picture so well known in 1917 and succeeding years Levaditi (1922) was able to prove by animal inoculation that the virus of encephalitis from human cases retained its activity long after the onset of the disease Hall (1024) suggests that the virus can lie quiescent for a long time and be reactivated from time to time It is difficult to explain why "idiopathic" cases are on the increase , conceivably they are a late result of the epidemic encephalitis of 1917–18 Encephalitis lethargica was a new disease at that time, but there were other epidemics in the past whose nature we do not know, and in some of these disorders of sleep were

IDIOPATHIC AND TRAUMATIC NARCOLEPSY

By A Wilson Gill, M D Edin , M R C P
PHYSICIAN TO THE NORTH STAFFORDSHIRE ROYAL INFIRMARY

TODAY the term narcolepsy is reserved for cases in which there are attacks of uncontrollable sleep, often without known cause The name was first used in this connexion by Gelineau (1800) and similar cases were described by Westphal (1877) and Fischer (1878) In Gelineau's case, the attacks of sleep were associated with attacks of sudden weakness of the legs, to which Henneberg (1916) gave the name cataplexy This is the combination of symptoms still occasionally known as Gelineau's disease and now implied by the term narcolepsy Kinnier Wilson (1928) records that he saw one case in 1907 and failed to find another typical case in the next twenty years, and Spiller (1926) had the same experience Adie (1926), on the other hand, was able to collect 20 cases, and described the disease as by no means very rare, later (Adie 1930) he reported 50 cases Within the last few years, cases have become more common and it is doubtful if this increase can be explained merely by more frequent recognition At the Mayo Clinic a steady increase is reported in the last 10 years

Hypersomnia is often a symptom in organic disease of the brain, especially in tumours of the third ventricle and in the region of the hypothalamus In the serious epidemic of encephalitis of 1917, sleep disturbance was such a frequent concomitant, that it was not surprising to find pathological changes in the hypothalamic region (Economo 1923) Dubois (1896) first suggested that there was an actual " sleep centre " in the floor of the aqueduct and third ventricle Recently a third-ventricle syndrome has been postulated which includes, in addition to hypersomnia and sudden attacks of weakness of the legs, a series of vegetative symptoms due to involvement of the adjacent nuclei of the hypothalamus , these may be disturbances of temperature or of water balance producing polydipsia and polyuria, of the appetite causing bulimia, of the reproductive system causing disturbances in menstruation, and of fat storage causing adiposity It is rare to find all these symptoms present in any one case Certainly typical cases, similar to Gelineau's case, have followed in the wake of genuine encephalitis, though they are few (Hall 1924, Adie 1926)

If the syndrome of narcolepsy with cataplexy can be a direct sequel to organic disease—such as tumours or encephalitis in the region of the third ventricle—we should also expect to find it occasionally, after trauma to the skull, as a result of minute hæmorrhages and subsequent softening of the hypothalamic region I am able to add 3 cases of traumatic narcolepsy to the few already recorded

SO-CALLED IDIOPATHIC NARCOLEPSY

Gelineau's case was a cooper, aged 38, who had an intense inclination to fall asleep even during meals, and would suddenly lose the power of his legs on laughing heartily or on feeling any other pleasurable emotion He could be awakened from his sleep if shaken violently, and at once he was wide awake, his head clear This shows the usual picture The association of the cataplectic attacks with emotion (laughter, anger) are common but seizures can occur independently of emotion In the attacks the patient is utterly powerless to move, he becomes a " mass of toneless muscle ", usually the paresis is general, sometimes localised (one arm, both legs, jaw) The attacks seldom last long enough for a full neurological examination to be made, but Kinnier Wilson (1928) was able to record in one case that the pupils reacted to light, slightly but definitely, no corneal reflex was present, the knee-jerks were completely abolished on both sides and the plantar reflex on one exposed foot was extensor These are remarkable observations considering the attack only lasted about 90 seconds Attacks lasting 15 min , as reported by Quensel (1925) and others, are unusual Attacks of cataplexy are so commonly brought on by laughter that many patients hold themselves in check and will not dare a hearty laugh It is doubtful whether the narcoleptic attacks are really sleep attacks , most patients are completely unconscious during then, but some can afterwards report all that went on though they had been powerless to answer or speak except for an occasional grunt Superficially the patients appear to be in a natural sleep , some will awake to a light touch or a call, others require more strenuous stimulation Most on awakening declare they are quite fresh and are at once wide awake, but some are irritable, mentally dull or even angry, as if their needs had not been duly satisfied The attacks usually come on without warning, but anything tending to induce sleep—such as a heavy dinner or the monotonous hum of a motor-car—will cause sleep more readily than normally The patient usually feels an imperious desire to sleep which cannot be resisted and is often dreamless The usual nocturnal sleep is not influenced and dreams occur as usual An attempt to resist the narcoleptic attack may bring on an attack of cataplexy Usually both attacks coincide, but either may occur without the other Certain personality changes have been noted in cases of narcolepsy Depression is exceptional, but irritability and argumentativeness, poor memory and poor concentration are common The following case is typical

CASE 1 —A woman, aged 30, training to be a teacher, while on holiday at the seaside in July, 1929, suddenly developed attacks of uncontrollable sleep and weakness of the legs She would sleep on a chair, in tramcars, in shops and on the sea front, she was also emotionally upset and would readily burst into tears After 2 weeks both kinds of attack had passed off, but on returning to work she could not attend to the lectures and in 1930 was advised to give up the idea of becoming a teacher During this time, her menstrual function, previously regular, became irregular and painful and remained so till 1938 There was no history of influenza or other acute illness and no reason to suspect a previous attack of encephalitis In 1931 she started to train as a nurse, apart from being easily tired, she was well In 1932 the narcoleptic attacks recurred She slept during meals, in writing letters, on buses and in her lectures At first by a great mental effort and by hurrying about, she could avert the attacks, but soon they became irresistible and could not be denied. If she was left alone the sleep attacks would last about a quarter of an hour, but gross stimulation with a pin would successfully shorten an attack The attacks were frequent and dreamless yet she slept and dreamed normally at night She awoke clear unless awakened forcibly, when she tended to be irritable and would yawn a lot In 1934 the cataplectic attacks recurred " My legs would suddenly feel weak especially if I was angry or amused Both hands felt weak and I would often spill cups of tea I never fell down and it was all over in a second " Narcolepsy and cataplexy occurred independently of each other, the latter being usually induced by laughter She had no other symptoms and no pathological signs Treatment by ephedrine had no effect in 1934 In 1938 a temporary improvement followed the use of Benzedrine and she improved still more on caffein in 1939 By this time, however, she was obviously beginning to improve and in 1940 the cataplectic attacks had completely disappeared while she was still taking caffein 5 gr daily She still complains of paræsthesia over the facial muscles but she had only three attacks of narcolepsy in the last year

The sudden onset in this case was curious There was nothing in her past or her family history to explain it, she was normally of a placid disposition and only showed *irritability if forcibly awakened* Her powers of concentration are still not good, but she is a capable nurse and is now attending maternity cases in hospital Similar cases have been reported (Adie 1926, Kinnier Wilson 1928, Daniels 1934)

TRAUMATIC CASES

In the case of an injury to the head followed by narcolepsy, damage to the third ventricle and hypothalamus might be expected Cases of traumatic narcolepsy with cataplexy have been reported from time to time in which symptoms have developed immediately after the injury to the head or a short time later This

IDIOPATHIC AND TRAUMATIC NARCOLEPSY

By A Wilson Gill, M D Edin , M R C P
PHYSICIAN TO THE NORTH STAFFORDSHIRE ROYAL INFIRMARY

Today the term narcolepsy is reserved for cases in which there are attacks of uncontrollable sleep, often without known cause The name was first used in this connexion by Gelineau (1800) and similar cases were described by Westphal (1877) and Fischer (1878) In Gelineau's case, the attacks of sleep were associated with attacks of sudden weakness of the legs, to which Henneberg (1916) gave the name cataplexy This is the combination of symptoms still occasionally known as Gelineau's disease and now implied by the term narcolepsy Kinnier Wilson (1928) records that he saw one case in 1907 and failed to find another typical case in the next twenty years, and Spiller (1926) had the same experience Adie (1926), on the other hand, was able to collect 20 cases, and described the disease as by no means very rare, later (Adie 1930) he reported 50 cases Within the last few years, cases have become more common and it is doubtful if this increase can be explained merely by more frequent recognition At the Mayo Clinic a steady increase is reported in the last 10 years

Hypersomnia is often a symptom in organic disease of the brain, especially in tumours of the third ventricle and in the region of the hypothalamus In the serious epidemic of encephalitis of 1917, sleep disturbance was such a frequent concomitant, that it was not surprising to find pathological changes in the hypothalamic region (Economo 1923) Dubois (1896) first suggested that there was an actual " sleep centre " in the floor of the aqueduct and third ventricle Recently a third-ventricle syndrome has been postulated which includes, in addition to hypersomnia and sudden attacks of weakness of the legs, a series of vegetative symptoms due to involvement of the adjacent nuclei of the hypothalamus , these may be disturbances of temperature or of water balance producing polydipsia and polyuria, of the appetite causing bulimia, of the reproductive system causing disturbances in menstruation, and of fat storage causing adiposity It is rare to find all these symptoms present in any one case Certainly typical cases, similar to Gelineau's case, have followed in the wake of genuine encephalitis, though they are few (Hall 1924, Adie 1926)

If the syndrome of narcolepsy with cataplexy can be a direct sequel to organic disease—such as tumours or encephalitis in the region of the third ventricle—we should also expect to find it occasionally, after trauma to the skull, as a result of minute hæmorrhages and subsequent softening of the hypothalamic region I am able to add 3 cases of traumatic narcolepsy to the few already recorded

SO-CALLED IDIOPATHIC NARCOLEPSY

Gelineau's case was a cooper, aged 38, who had an intense inclination to fall asleep even during meals, and would suddenly lose the power of his legs on laughing heartily or on feeling any other pleasurable emotion He could be awakened from his sleep if shaken violently, and at once he was wide awake, his head clear This shows the usual picture The association of the cataplectic attacks with emotion (laughter, anger) are common but seizures can occur independently of emotion In the attacks the patient is utterly powerless to move, he becomes a " mass of toneless muscle " , usually the paresis is general, sometimes localised (one arm, both legs, jaw) The attacks seldom last long enough for a full neurological examination to be made, but Kinnier Wilson (1928) was able to record in one case that the pupils reacted to light, slightly but definitely, no corneal reflex was present, the knee-jerks were completely abolished on both sides and the plantar reflex on one exposed foot was extensor These are remarkable observations considering the attack only lasted about 90 seconds Attacks lasting 15 min , as reported by Quensel (1925) and others, are unusual Attacks of cataplexy are so commonly brought on by laughter that many patients hold themselves in check and will not dare a hearty laugh It is doubtful whether the narcoleptic attacks are really sleep attacks , most patients are completely unconscious during then, but some can afterwards report all that went on though they had been powerless to answer or speak except for an occasional grunt Superficially the patients appear to be in a natural sleep , some will awake to a light touch or a call, others require more strenuous stimulation Most on awakening declare they are quite fresh and are at once wide awake, but some are irritable, mentally dull or even angry, as if their needs had not been duly satisfied The attacks usually come on without warning, but anything tending to induce sleep—such as a heavy dinner or the monotonous hum of a motor-car—will cause sleep more readily than normally The patient usually feels an imperious desire to sleep which cannot be resisted and is often dreamless The usual nocturnal sleep is not influenced and dreams occur as usual An attempt to resist the narcoleptic attack may bring on an attack of cataplexy Usually both attacks coincide, but either may occur without the other Certain personality changes have been noted in cases of narcolepsy Depression is exceptional, but irritability and argumentativeness, poor memory and poor concentration are common The following case is typical

Case 1 —A woman, aged 30, training to be a teacher, while on holiday at the seaside in July, 1929, suddenly developed attacks of uncontrollable sleep and weakness of the legs She would sleep on a chair, in tramcars, in shops and on the sea front , she was also emotionally upset and would readily burst into tears After 2 weeks both kinds of attack had passed off, but on returning to work she could not attend to the lectures and in 1930 was advised to give up the idea of becoming a teacher During this time, her menstrual function, previously regular, became irregular and painful and remained so till 1938 There was no history of influenza or other acute illness and no reason to suspect a previous attack of encephalitis In 1931 she started to train as a nurse, apart from being easily tired, she was well In 1932 the narcoleptic attacks recurred She slept during meals, in writing letters, on buses and in her lectures At first by a great mental effort and by hurrying about, she could avert the attacks, but soon they became irresistible and could not be denied. If she was left alone the sleep attacks would last about a quarter of an hour, but gross stimulation with a pin would successfully shorten an attack The attacks were frequent and dreamless yet she slept and dreamed normally at night She awoke clear unless awakened forcibly, when she tended to be irritable and would yawn a lot In 1934 the cataplectic attacks recurred " My legs would suddenly feel weak especially if I was angry or amused Both hands felt weak and I would often spill cups of tea I never fell down and it was all over in a second " Narcolepsy and cataplexy occurred independently of each other, the latter being usually induced by laughter She had no other symptoms and no pathological signs Treatment by ephedrine had no effect in 1934 In 1938 a temporary improvement followed the use of Benzedrine and she improved still more on caffein in 1939 By this time, however, she was obviously beginning to improve and in 1940 the cataplectic attacks had completely disappeared while she was still taking caffein 5 gr daily She still complains of paræsthesia over the facial muscles but she had only three attacks of narcolepsy in the last year

The sudden onset in this case was curious There was nothing in her past or her family history to explain it , she was normally of a placid disposition and only showed irritability if forcibly awakened Her powers of concentration are still not good, but she is a capable nurse and is now attending maternity cases in hospital Similar cases have been reported (Adie 1926, Kinnier Wilson 1928, Daniels 1934)

TRAUMATIC CASES

In the case of an injury to the head followed by narcolepsy, damage to the third ventricle and hypothalamus might be expected Cases of traumatic narcolepsy with cataplexy have been reported from time to time in which symptoms have developed immediately after the injury to the head or a short time later This eriod every 15 minutes for one hour Then eserine as given, and records were obtained under identical onditions every 15 min for the next two hours to etermine the effect of the drug

The method was used to observe the effect of anti-holinesterases in these epileptic outbursts, because there as recently been increasing interest in the effect of holinergic substances on the activity of the central ervous system Schweitzer, Stedman and Wright 1939) have reported changes in the motor activity of the pinal cord after introducing anticholinesterases into the pinal theca, and Miller (1937), Bremer (1938), and Miller, Stavraky and Woonton (1940) have reported hanges in cerebral electrical activity after the introduction of eserine, acetylcholine and atropine into the cortex More recently McKail, Obrador and Wilson (1941) have found striking alterations in the responses to electrical stimulation of the motor cortex after these substances have been injected into the carotid artery

All this work on cerebral activity has been based on open experiments in animals The cortical electrical discharges of the epileptic offer an opportunity to carry this work further by making observations on human subjects, and it is possible that any result obtained might be applied to the study of the ætiology of epilepsy

This paper describes the method used and the results obtained with eserine and Prostigmin

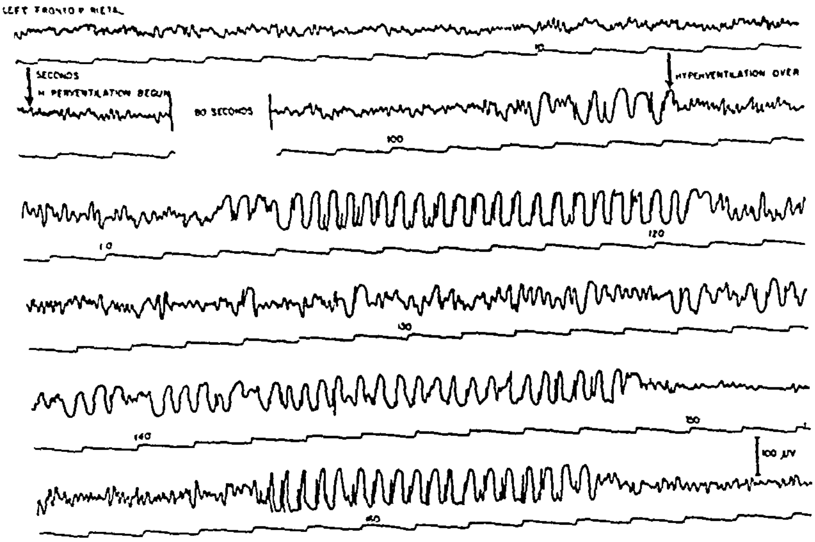

FIG 1—A continuous electroencephalogram from the left hemisphere of a patient with petit mal epilepsy The record reads from left to right, and from above downwards Time is in seconds Overbreathing for 100 sec produced a small outburst of large waves with a frequency of two a second This was followed in 8 sec by alternating spikes and waves characteristic of petit mal There were two further outbursts before the record returned to normal The total time occupied by these epileptic discharges after similar periods of overbreathing was used to determine the effect of eserine and prostigmin on petit mal

EXPERIMENTAL METHOD

Epileptic subjects and normal controls were used A pair of electrodes were sealed to the scalp with collodion simplex, contact being made with Cambridge electrode jelly The electrodes were connected to a condenser-coupled amplifier which motivated an ink-writing oscillograph from which continuous records were obtained on moving paper (fig 1) One electrode was placed at the hair line over the frontal lobe and the other over the parieto-occipital region, so that they recorded changes taking place over a large area of cortex Spontaneous epileptic attacks—even the more frequent subclinical ones—are usually so capricious in their appearance that they are not reliable for experimental purposes Data were therefore obtained from attacks induced by raising the pH of the blood by hyperventilation (Gibbs, Gibbs and Lennox 1939) The patient was shown how to hyperventilate and it was found that steady overbreathing for 100 seconds was enough to produce an epileptic outburst of a petit-mal type in the subjects used The subjects were instructed to hyperventilate for 100 sec every 15–20 min and to try to maintain the same depth of overbreathing each time The experimental procedure calls for considerable intelligent cooperation on the part of the subject and obviously requires careful selection of suitable patients

The respiratory rate was recorded while the expired air was collected in a Douglas bag and measured The experiments were begun about 3 hours after a meal, thus ensuring a fairly stable blood-sugar level, the subjects sat comfortably in a quiet room and repeated records were taken for periods up to 3 hours after an injection had been given The duration of the induced epileptic discharge was measured during and after each period of hyperventilation. Fig 1 shows the response of an epileptic subject's E E G to overbreathing Several epileptic outbursts often occurred after hyperventilation and they were occasionally associated with momentary changes in consciousness and behaviour The sum of their duration in seconds was taken to represent the total epileptic activity resulting from the preceding hyperventilation and this factor was plotted graphically after each experiment (see figs 2–5)

RESULTS WITH ESERINE

Epilepsy induced by overbreathing—Physostigmine salicylate (eserine) B D H was injected subcutaneously in doses of 1–2 mg in nine experiments on five subjects In seven this dose did not give rise to any symptoms, and in six of these seven there was a diminution in the epileptic activity after hyperventilation. This improvement began between 15 and 30 min after the injection and lasted for a further 50 min In two instances the improvement was maintained for more than 100 min. after the injection, at which time the experiment was discontinued The epileptic activity ceased completely in four experiments (fig 2) This prolonged remission in the epileptic outbursts will be referred to again later Examples of the changes obtained in the E E G are represented graphically in figs 2 and 3 In one instance there was no change in the epileptic activity occurring after overbreathing, and in the remaining experiment there was an increase in the epileptic activity after injection of 1 0 mg of eserine, although the subject had on two previous occasions shown a great improvement after 1 5 mg In the two instances where symptoms followed the injections there was an increase in the epileptic activity after overbreathing In one of these, injection of 1 5 mg of eserine was followed by an increase in the duration of epileptic discharges which began 20 min after the injection and passed off 60 min later. The subject then had slight abdominal discomfort and nausea The remaining subject received 3 0 mg and in 30 min became pale and cold, with sweating, salivation, nausea, colic and vomiting There was an increase in the epileptic activity which was maximal 70 min after the injection (fig 4)

Spontaneous epilepsy—An attempt was made to alter the incidence or duration of spontaneous epileptic discharges with eserine in six experiments on four subjects A dose varying between 1 and 2 mg was given on four occasions without any subsequent symptoms There was a reduction in the amount of spontaneous epilepsy in two and in the other two no significant change could be seen In two subjects who experienced some nausea and abdominal discomfort without vomiting there was a definite increase in the epileptic activity One man received 3 5 mg, and the other, a small boy of thirteen, 1 5 mg of eserine subcutaneously

RESULTS WITH PROSTIGMIN

Epilepsy induced by overbreathing—Prostigmin was given on eight occasions to four subjects In seven experiments 1 5 mg was injected subcutaneously and in one 2 mg was given In all the experiments there was a significant increase in the epileptic activity seen striking—for example, in the epidemic in Tubingen in 1712–13, the disease known as nona in Italy in 1889–90, and Dubini's electric chorea in Italy in 1846 The number of cases in which narcolepsy can be associated with a definite encephalitis are relatively few The usual sequel of encephalitis is parkinsonism Adie (1926) in his series of 20 cases mentions 2 patients in whom narcolepsy and cataplexy followed encephalitis lethargica, one a boy of 17 and one a man of 20 Pollock (1930) reports the case of a girl who after an attack of encephalitis lethargica developed narcolepsy with sudden *attacks, associated with laughter, of muscular hypotonus* causing her to fall to the ground

Disturbances of sleep occur in organic diseases of the brain, other than encephalitis Pette (1923) found an area of softening in the tegmentum, between the substantia nigra and the aqueduct, in a man who lay asleep for three months prior to his death Luksch (1924) reported a case of infective endocarditis complicated by continuous sleep for a fortnight before death, and found at necropsy an embolic abscess in the grey matter of the caudal part of the third ventricle and in the wall of the aqueduct Soca (1900) reported the case of a girl of 18 with prolonged sleep where a tumour was found penetrating into the third ventricle and Righetti (1903) has reported a similar case Jefferson and Harvey Jackson (1939) have reported the effects of a series of tumours and summarised the symptoms of third ventricular syndrome In narcolepsy it may safely be assumed that the lesion, whatever it may be, involves this region, and that trauma affecting that part of the brain is capable of producing any of the symptoms, including narcolepsy, cataplexy, polydipsia, bulimia, personality changes and disturbances of the menstrual cycle In war-time, when skull injuries will be common, traumatic cases are likely to occur And it is also worth nothing that the recognition of narcolepsy in non-traumatic cases may save an occasional soldier from punishment if found asleep at his post

The prognosis is uncertain in all cases, but the chances of recovery are probably greater in the traumatic than in the encephalitic variety Treatment is unsatisfactory Some patients improve on ephedrine, benzedrine or caffeine Daniels found that one patient improved after encephalography, but this has not given constant results in other cases The absence of physical signs and the tendency to laugh and sing in the attacks (as illustrated in one of my cases) has caused some observers to suspect a hysterical basis for narcolepsy, but the symptoms cannot be evoked by suggestion and no permanent effect has been produced by psychotherapy or psycho-analysis Gillespie (1927) has reported on a case of cataplexy (without narcolepsy) as having improved with modern psychotherapy, but the results were not lasting

SUMMARY

Narcolepsy is a symptom complex, not a disease In the absence of tumour or other gross pathology, narcoleptic symptoms are often the result of a localised mild encephalitis due to an attenuated form of the virus Most cases give no history of such an acute illness, but narcolepsy and cataplexy may occur in the course of, or following, an attack of epidemic encephalitis

Trauma to the skull may be expected to cause similar effects if damage is localised in the region of the hypothalamus and the third ventricle Three cases are described in which it is fair to assume that the accident to the skull was the responsible factor

Such cases are organic, and not, as still described in some textbooks, hysterical Symptoms produced by suggestion may be superadded, as they may in any *organic disease, and may be removed by superficial* psychotherapy There is no case yet on record where the whole picture has been altered or improved materially by psychotherapy even by deep analysis

I am indebted for the notes of cases to Dr Bruce MacLean, Dr J A Davenport and Dr C H Young

ACTION OF ESERINE AND PROSTIGMIN ON EPILEPTIC CEREBRAL DISCHARGES*

BY

DENIS WILLIAMS,

MAJOR, R A M C

(*From the Military Hospital for Head Injuries*)

EPILEPTIC *attacks are accompanied* by outbursts of cortical electrical activity which can easily be recognised by electroencephalography (Gibbs, Lennox and Gibbs 1936) These outbursts are sharply delimited and are made up of a rhythmic pattern of waves whose form varies with the type of epilepsy Their size and duration have a direct relationship to the severity of the clinical attacks but short outbursts with similar wave forms are often seen without any clinical accompaniment These small attacks disturb the rhythm of cerebral electrical activity as seen in the electroencephalogram (E E G) but are not large enough to interfere with consciousness or to produce any clinical concomitant They have therefore been called subclinical or "larval" attacks (Gibbs, Gibbs and Lennox 1937) These subclinical attacks may occur at short intervals even though the clinical fits are infrequent This is particularly the case in petit mal, where outbursts of a characteristic type are seen (fig 1) The ratio of subclinical to clinical attacks varies greatly from patient to patient but in any one subject it is fairly constant Thus the anticonvulsant effect of a drug can be assessed by observing the amount of epileptic activity occurring in a few minutes in the E E G record, and the study of this activity provides an experimental method for the study of epilepsy

These subclinical epileptic attacks have been used by Gibbs, Lennox and Gibbs (1940) as a measure with which to investigate the effect of alterations in blood gases, blood pH and blood-sugar (Gibbs, Gibbs and Lennox 1939) on the incidence of epilepsy These workers found that petit-mal activity is readily induced by a fall in blood-sugar or by an alteration of the acid-base balance to the alkaline side Such an alteration in acid-base balance can be conveniently caused by overbreathing and it has been found that hyperventilation in cases of petit mal is usually followed in a few seconds by a subclinical attack This procedure is useful for diagnostic purposes and it has been used in the present study in the following manner

Cooperative patients were asked to overbreathe at a fixed rate, with the same respiratory excursion and for the same length of time every 10 or 15 minutes The amount of epileptic activity resulting was assessed by measuring the time on the E E G record taken up by characteristic abnormal wave forms (fig 1) The effect of various drugs on the amount of epileptic activity resulting from a known precipitating cause could then be observed For instance a record was obtained from a subject with petit mal who overbreathed for a fixed

eserine the dose was too small to modify this increment

DISCUSSION

The opposite effect of small doses of eserine and prostigmin on the cortical electrical disturbances associated with epilepsy is most striking It may depend on a different mode of action within the central nervous system, for Schweitzer, Stedman and Wright (1939) have pointed out that eserine is a tertiary ammonium base which is fat soluble and therefore may enter the parenchymal cells, whereas prostigmin is a quaternary ammonium base and being water soluble exerts its maximal effect outside the cell, possibly at the synapse The first is a central convulsant, but petit mal, with which this paper is concerned, may well be the result of simple depression of nervous activity, so that the present results are not necessarily at variance with those of Schweitzer and Wright (1937) who found that eserine caused an increase in spinal activity while prostigmin depressed it The present results may, on the other hand, depend on the peripheral changes produced by eserine and prostigmin, but this is unlikely since both have a similar peripheral parasympatheticomimetic action Although changes in blood-sugar have been reported (Hrubetz 1937), the doses used in these experiments were apparently not large enough to produce any significant change Petit mal can readily be produced by raising the blood pH, but the amount of overbreathing necessary to produce attacks was constant in these experiments, although the alterations in epileptic activity were considerable This suggests that a change in the blood pH was not the cause of the results obtained Further and more precise observation of the blood pH will be necessary to establish this observation A point in favour of a causal relationship between the blood pH and the increase in epileptic activity with prostigmin and eserine might be the association of nausea and vomiting with the changes seen in the E E G Vomiting results in a depletion of HCl with a shift of acid from blood to stomach and consequent temporary alkalosis Such a condition would favour the production of petit-mal epilepsy, but several of the subjects in this investigation showed increased epileptic activity without any symptoms, so that the change is probably unimportant

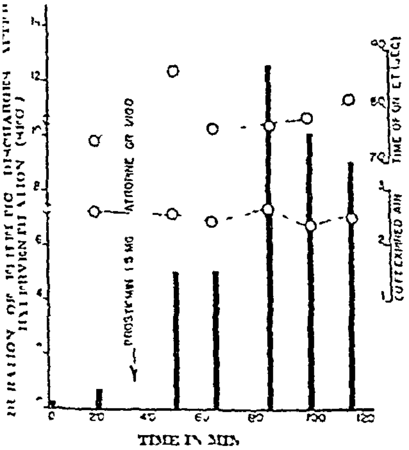

FIG 5—The effect of 1 5 mg of prostigmin with gr 1/100 atropine subcutaneously on petit-mal activity induced by repeated standard periods of overbreathing (100 sec) The volume of air expired during the overbreathing and the time of onset of the attacks has no constant relationship to the amount of epileptic activity

It is so far impossible to localise the site of action of the anticholinesterases in petit-mal epilepsy, but it has been shown that several peripheral effects of the substances are not causally related to the changes observed There is chemical and experimental support for the suggestion that the action is a central one (Schweitzer, Stedman and Wright 1939) but more data are required to establish this hypothesis

In view of the beneficial effects of small doses of eserine, clinical trial has been undertaken in a few selected cases Some have had striking temporary remissions, and a larger group is being studied At the most the results justify a further study of the rôle played by the cholinergic mechanism in the initiation or maintenance of epileptic cerebral activity.

SUMMARY

In six out of seven experiments carried out on epileptic patients eserine in doses not large enough to cause symptoms reduced the petit-mal activity seen in the E E G With large doses the epileptic activity was increased

Prostigmin invariably caused an increase in the petit-mal activity in ten experiments The effect of eserine was reversed by prostigmin and the effect of prostigmin and of large doses of eserine was abolished by atropine

Other factors known to precipitate petit-mal epilepsy were controlled and the results suggested that the effect may be a central one, but further work is being undertaken to attempt to establish the mode of action

A study of the effects of other autonomic drugs on the electrical activity of the cerebral cortex offers a new approach to the investigation of the ætiology of epilepsy

We are grateful to Lieut Colonel G O Chambers, R A M C, for permission to publish the data included in this paper, to the medical officers for coöperating in the work, and to Miss J K Reynell, B Sc, for technical assistance The apparatus used in the experiments has been lent to the Royal Air Force by the National Hospital, Queen Square, and a grant towards the expenses incurred has been made by the Medical Research Council

MENINGITIS WITH NASAL DISEASE

DUE TO STREP. VIRIDANS

By D R Cameron, M D St And
ASSISTANT PHYSICIAN TO YORK COUNTY HOSPITAL

The following case seems sufficiently rare, both in its incidence and its fortunate ending, to be worth recording

A boy, aged 9 years, had had a transient pharyngeal infection, from which he had recovered quickly, and apparently completely The illness here recorded started suddenly 3 weeks later, with headache, vomiting, and rise of temperature to 103° F When I first saw him, about 36 hours after the onset, he was hardly conscious, restless, and resentful of any interference Considerable head retraction was present, with Kernig and Brudzinski signs positive There was distinct puffiness below the left eye, and the movements of the eyeball were limited He was removed to the York City Fever Hospital, where a *lumbar puncture* was done The cerebrospinal fluid was under considerable pressure, turbid, and contained numerous pus cells and gram-positive cocci, which culture showed to be streptococci of the viridans type Treatment was begun with 1 g of sodium sulphapyridine intramuscularly followed by 1 g of sulphapyridine every four hours by mouth. On account of the eye signs, a radiogram was taken of the nasal sinuses, and this indicated an infection of both maxillary antra As the patient continued to be desperately ill, Mr R Thomas, on the evening after admission, punctured both antra and drained the left, which contained pus, opened and drained the left frontal sinus, on the floor of which a little pus was found, and exenterated the left ethmoid, which was necrotic At the same time similar amounts of Soluseptasine were substituted for the sulphapyridine Cultures from the infected sinuses were made, and a *Streptococcus viridans* again found

During the next two days the boy's condition steadily improved, and this improvement continued On the third day after operation a lumbar puncture showed fluid with 200 cells per c mm, mostly lymphocytes, cultures sterile After 18 g. in all of the sulphonamides had been given, a leucopenia was found (4500 white cells per c mm) The drug was stopped and 5 c cm of *pentnucleotide* was given, and in five days the white count had risen to 8700 Eighteen days after admission the patient was well enough to be discharged in the E E G In three cases there were no symptoms, but in five the characteristic symptoms of nausea and abdominal discomfort arose, requiring subcutaneous injection of atropine sulphate in four cases A typical result is shown in fig 5

Spontaneous epilepsy—Prostigmin was given subcutaneously in doses of 0 6 mg and 1 5 mg in two subjects In both there was an increase in the incidence and duration of the spontaneous attacks One had nausea and abdominal discomfort, the other was symptom-free

RESULTS WITH ESERINE FOLLOWED BY PROSTIGMIN

In two experiments an injection of 1 5 mg of eserine produced a decrease in epileptic activity 1 5 mg of prostigmin was then injected and the decrease was altered to an increase above the initial level In one of these experiments induced attacks were used and in the other spontaneous attacks

RESULTS WITH ATROPINE

Small doses of atropine sulphate (gr 1/150) given simultaneously with eserine or prostigmin did not seem to modify the results Gr 1/100 atropine reduced the amount of epileptic activity induced by overbreathing when injected after an increase had been produced by prostigmin, and a similar dose used independently reduced the number of induced and spontaneous attacks The results with atropine will be reported in detail later

MODE OF ACTION

The effect of eserine and prostigmin in modifying epileptic activity may be central or peripheral The following possible factors were investigated

Respiratory exchange—Epileptic activity would increase if the respiratory exchange were facilitated, for washing out CO_2 would raise the blood pH When possible the depth of overbreathing was determined by measuring the expired air which had been collected in a Douglas bag system during each period of hyperventilation There was no significant alteration in the total volume of gaseous exchange during 100 sec hyperventilation in thirteen experiments with large and small doses of eserine and prostigmin (see figs 4 and 5) The individual variations were no greater than those obtained in a series of control experiments without drugs On the other hand, it was surprising how uniformly a cooperative subject could maintain a steady level of hyperventilation in repeated experiments

Blood-sugar—An increase in epileptic activity might have been caused by a fall in blood-sugar (Gibbs, Gibbs and Lennox 1939) Samples of blood were therefore removed after each period of overbreathing and the blood-sugar estimated by the Folin-Wu method The doses of eserine and prostigmin used did not result in any constant change in the blood-sugar levels, although changes have been produced by larger doses (Hrubetz 1937) Details of the results obtained will be reported later

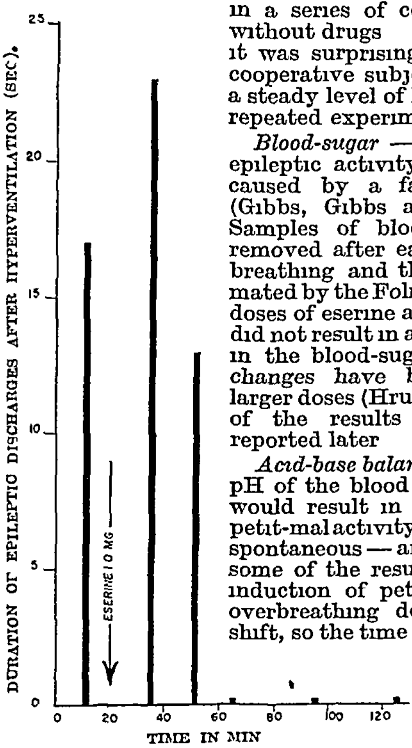

FIG 2—The effect of 1 mg of eserine on the number of seconds of petit mal activity induced by repeated standard periods of overbreathing in the subject whose record is shown in fig 1

Acid-base balance—A shift in the pH of the blood to the alkaline side would result in an increase in the petit-mal activity—both induced and spontaneous—and might explain some of the results obtained The induction of petit-mal epilepsy by overbreathing depends on such a shift, so the time of onset of epileptic activity after beginning overbreathing was measured in each case and was found to be remarkably constant in each experiment For instance, in one subject epileptic discharges were seen 54 ± 4 5 sec after beginning over-breathing, while in another 79 ± 6 5 sec were necessary, while the total gaseous exchange per min was 1 1 cu ft in the first and 1 5 cu ft in the second There seemed to be no relationship between the amount of epileptic activity induced by overbreathing and the change in blood pH necessary to produce it, as judged by the time of its onset during the period of overbreathing (figs 3 and 5) This was strong presumptive evidence that changes in the pH of the blood were not causally related to the changes obtained by the anticholinesterases In order to confirm this observation it will be necessary to determine the exact pH of the blood in the condition of the experiment For this, determinations with a glass electrode system and a direct coupled amplifier are being made

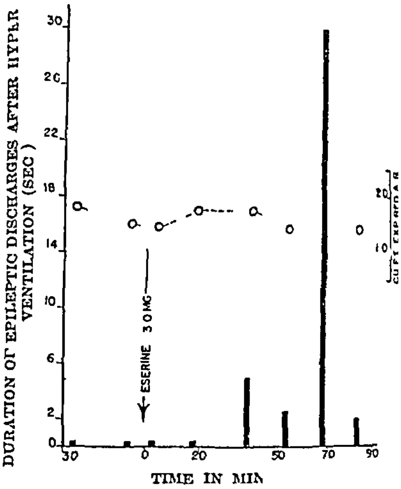

FIG 4—The effect of 3 mg of eserine on the same subject as in fig 2, under identical experimental conditions The volume of expired air represents the total respiratory exchange during 100 sec of overbreathing

Psychological factors—From clinical experience the distress associated with symptoms resulting from large doses of prostigmin or eserine might be expected to cause an increase in the incidence of fits Careful note was kept of the patient's state and his symptoms were noted as they arose A decrease in epileptic activity was never observed when such symptoms were present, but an increase occurred with prostigmin in four experiments in the absence of any clinical sequelæ of the injection In the other cases symptoms were associated with the increase in epileptic activity

RESULTS IN CONTROLS

Eserine and prostigmin did not produce any abnormal response in the E E G after overbreathing in three normal subjects The experimental procedure was repeated without any drugs in five of the patients and there was no constant change in the degree of epileptic abnormality after standard hyperventilation In three cases there was a gradual increase in the amount of abnormality with each repeated period of overbreathing The changes already described were independent of this effect, but it is possible that in the one subject who showed an increase in epileptic activity after 1

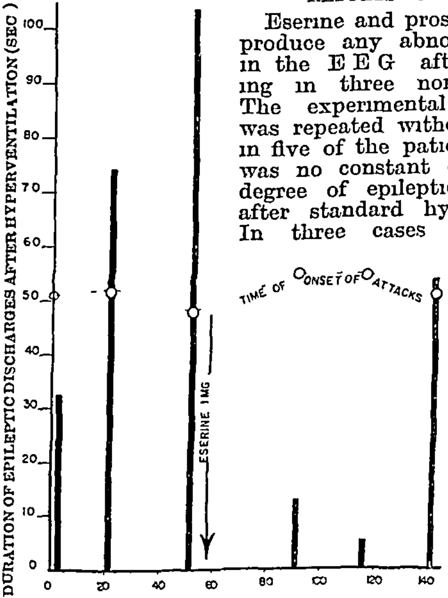

FIG 3—The effect of 1 mg of eserine on the number of seconds of petit mal activity induced by repeated standard periods of overbreathing In this subject repeated overbreathing caused a steady increase in the epileptic activity, in the absence of any drugs

On Dec 19 the abscess was needled and thick pus found. Culture: *Staphylococcus aureus*, no tubercle bacilli. Blood count: red cells 4,650,000, Hb 82%, white cells 6000 (polymorphs 71%). On Dec 30 the abscess was aspirated again, and 40 c cm of pus withdrawn. Culture as before. A diagnosis of staphylococcal osteomyelitis of the spine was made and the patient was immobilised in a plaster bed. By March 11, 1940, his temperature was still swinging and he was given a course of sulphapyridine, 25 g, blood sulphapyridine levels were: first day, 8 2 mg, second day, 11 65 mg, third day, 5 82 mg per 100 c cm. No clinical improvement was noted. On March 1 a course of sulphathiazole was given. A single dose of 2 g was followed by 1 g 4-hourly until a total of 25 g had been given, blood-sulphathiazole levels were: first day, 4 71 mg, second day 11 35 mg per 100 c cm. After this course he continued to show steady improvement. On April 23 he was transferred to Claybury Emergency Hospital under the care of Mr L C Oliver. On Aug 1 he was removed from the plaster bed and put into a plaster jacket, which he wore for 6 weeks. By Nov 21 his general health was good and he weighed 9 st 13 lb. Radiography showed the abscess to have been absorbed and that there was bony fusion between the 5th and 6th dorsal vertebræ. His weights during treatment were: Dec 28, 1939, 7 st 4 lb, Jan 10, 1940, 7 st 5 lb, March 9, 7 st 9 lb, Nov 21, 9 st 13 lb. The erythrocyte sedimentation rates (Westergren) were: Jan 2, 104, Jan 12, 61; March 15, 75; April 8, 50, Nov 21, 7.

This type is most often seen in adults. The onset is more gradual and the symptoms are from the first referred to the affected vertebra. Unless the organism is isolated from an abscess or from some pyæmic focus elsewhere in the body these cases may be diagnosed as tuberculosis of the spine. Some have been treated by bone-grafting with excellent results. Two cases of this type have been treated at the London Hospital in the last two decades. The first had a bone-graft performed for supposed tuberculous infection but later developed staphylococcal abscesses in other bones, the second was treated by aspiration of a spinal abscess with immobilisation of the spine. Both recovered. We have presented this case to illustrate the difficulties in diagnosis in this type of spinal infection and also to show that chemotherapy may play a part in the treatment. Improvement certainly followed the administration of sulphathiazole but there was no striking difference in the clinical course of the disease, as compared with that seen in similar cases. Blood-cultures were not done because the patient did not show the clinical picture of septicæmia. Up to the present we have not had the opportunity of treating a fulminating case with chemotherapy and as far as we know no such case has been published since sulphathiazole came into use.

We would like to thank Dr W R Thrower for help and advice, and Messrs May and Baker for supplying sulphathiazole (Thiazamide).

PLASTERS WITHOUT TEARS —The slab technique for application of plaster-of-paris casts, using standard patterns, saves both time and mess, and Messrs T J Smith and Nephew Ltd have done useful service in summarising present practice in a booklet "Preparation of Plaster Casts" and in offering a set of patterns to users of their wide "Cellona" material. The technique described in the booklet agrees with that recommended by Trueta, G R Girdlestone (*Lancet*, 1940, 2, 287) and W S Creer (*Ibid* Jan 4 1941, p 9). On page 4 it would have been well to have explained the reason for leaving a narrow gap between adjacent edges of slabs. This allows the plaster to expand if the limb swells after its application, and is thus a valuable safeguard against the danger of constriction of the circulation. The shoulder-spica pattern could be improved by cutting out a semicircle for the neck. Nursing of the patient in plaster is perhaps outside the scope of this brochure, but though the success of plaster work depends on good patterns and good application it depends almost as much on watchful care and ex t nursing after the plaster is applied.

Medical Societies

ROYAL SOCIETY OF MEDICINE

AT a meeting of the Section of Epidemiology and State Medicine on March 28 with Dr WILLIAM BUTLER in the chair, a discussion on

Pulmonary Tuberculosis in the Royal Navy

was opened by Surgeon Rear-Admiral S F DUDLEY F R S. He described how up to 1900 the incidence of tuberculosis in the Navy shared in the decline of this disease in the general population. Since 1900 in spite of the continued fall for the country as a whole the case-incidence in the Navy has remained at about 2 per 1000 although the greatest efforts have been made to ameliorate the environment by better ventilation, dust-extraction and improved diet, and to improve diagnosis by periodic overhauls of the men. This apparently critical morbidity is about twice that in the Army and R A F. and is higher than in comparable sections of the civilian population although the Navy is a selected body of men. Among the officers the morbidity is less than half that among the ratings, and ratings who become officers share in the reduction, while those who remain on the lower deck maintain their old higher rate. These findings suggest that an important factor in preventing improvement in the Navy is overcrowding—i e, allotment of space for work and for sleeping accommodation. Little further reduction in overcrowding can be expected—there is a tendency for an increase of the ratio of machinery to men in the development of modern warships. The problem before the Navy is therefore to detect latent tuberculosis before the patient becomes ill and coughs up tubercle bacilli. For this purpose ordinary physical examinations have been proved useless and new methods must be found which are cheap and rapid. The whole naval force must be examined periodically and not just on entry as recruits. This is feasible since tuberculosis appears to be contracted on the ships themselves—the whole ship's company form the home-contacts of any case—and the men change their ships every two to three years, at which time they could be conveniently examined at one of the three naval depots.

Miniature radiography Admiral Dudley said offers the method of choice and it was decided largely through the initiative of Surgeon Commander A Robinson Thomas to X ray the whole naval force on every change of commission. The first miniature-radiography department was opened under Surgeon Commander W G C Fitzpatrick at Chatham and the statistics of the first 18,000 men examined are presented. Over 100 suspects were found, but following the principle of X raying with a full-size film all suspected cases this number was reduced considerably. In all 69 cases were sent to hospital and 47 of these were finally diagnosed as active tuberculosis and invalided out making a final case-incidence of 2 per 1000. Half the active cases had positive sputum which is an improvement on the 90% usually found in the Navy by the ordinary methods of diagnosis. It is hoped that the percentage of sputum-negative cases will increase. Most of the men with active disease had no complaints. The incidence of suspected active tuberculosis on the miniature films was considerably higher for the older men than for the younger. Summing up, Admiral Dudley pointed out the advantage of the method both to the patient and to the naval community. He expected the case-incidence to increase at first owing to the number of unrecognised cases already present. The final efficacy will partly depend on how far tuberculosis in the adult is due to fresh infections and how far to the breakdown of resistance. It will also depend on what is the minimal dose required to produce disease in susceptible subjects.

Surgeon Commander FITZPATRICK, who organised the Chatham department, described its routine. A Stanley Cox unit is used with 35 mm film, 100 mA power, tube-screen distance of 36 in. and an exposure time of 0 3–0 6 sec. The cost per case is less than 1*d* and 200 cases can be examined in an hour.

Surgeon Commander THOMAS pointed out that the method is as useful for the community as a whole as for the Navy and may reduce the high costs in life and money

Before the sulphonamides were used, the fatality in cases of this kind approached 100% Hagerup (1936) reported two recoveries in meningitis following ethmoiditis, but the symptoms in these cases were comparatively slight Appelbaum (1938), however, reports one case of recovery from severe meningitis caused by the *Strep viridans* following ethmoidal infection, and treated with sulphonamides and spinal drainage without operation The time to operate, if operation is attempted, appears to be when localisation has occurred, as it had in this case Hagerup advises operation when a pleocytosis of the cerebrospinal fluid has appeared Bowers (1939) advises operation if signs of meningeal irritation are present Goodyear (1939) advises against operation until there is evidence of pus formation in the sinuses affected

In the case here described, it seems unlikely that the patient would have survived without the sulphonamides, though this class of drug is not generally supposed to have a dramatic effect on an infection with non-hæmolytic streptococci Of the two compounds used, soluseptasine appeared to be the more effective

My thanks are due to Mr Thomas, Dr S G Platts, Dr J N F Fergusson, and to Dr N J M Hession, for their help with this case

HODGKIN'S DISEASE IN THE BLADDER

By Ralph Phillips, M S Lond , F R C S , D M R E
RADIOTHERAPIST TO ST BARTHOLOMEW'S HOSPITAL, LONDON

In several hundred cases of Hodgkin's disease investigated and treated at St Bartholomew's Hospital, this particular manifestation in the bladder has not been seen before, and it seems to be the first case diagnosed in life and successfully treated Lebowich [1] recorded a case in which intermittent attacks of hæmaturia and frequency were the first symptoms , the presence of pyelonephritis and renal failure obscured the diagnosis, no treatment was given, and the patient died 20 months from the onset , autopsy showed a dense lymphadenomatous infiltration of the bladder, rectum and rectovesical pouch, and there were deposits in all the abdominal organs , enlargement of the cervical glands had been noticed during life, but had been taken to be metastases from a malignant process Lebowich found only 5 published cases of Hodgkin's disease in which involvement of the bladder had been recorded

In June, 1940, a man of 32, feeling absolutely well, presented himself before a medical board for service in the R A F , but was rejected because he had " lumps in the neck " A month later he noticed a slight but irritating rash on the lower limbs, and in August he began to suffer from frequency of micturition By the beginning of September the frequency had become hourly by day and night, and was accompanied by acute pain and a yellow discharge at the end of the act The urge to micturate became so frequent that it amounted to virtual incontinence, and after passing a few drops of blood on one occasion he came to hospital and was admitted on Sept 21

He was pale and looked ill, partly owing to loss of sleep from the pain and frequency The right cervical and right axillary lymph glands were greatly enlarged and were typical of lymphadenoma, the diagnosis being confirmed as lymphadenoma verum by biopsy , a radiogram of the chest showed enlargement of the mediastinal glands also Apart from the rash on the lower limbs and deep tenderness in the suprapubic region there were no other physical signs , the temperature was normal, but the pulse rate was raised to 110 The white-cell count was 19,600 per c mm , and there was an eosinophil count of 980 per c mm (5%) The urine was sterile on culture, and no tubercle bacilli were found X-ray therapy to the thorax and neck was begun on Oct 28, and, on the supposition that there was a subacute non specific cystitis which had not yielded to the usual measures, doses of 50 r *were given to the bladder at 5 day intervals* The enlarged glands rapidly decreased in size, but the pain and frequency persisted On Nov 14 cystoscopy by Mr Kenneth Walker showed the mucous membrane of the bladder to be studded with greyish-yellow nodules the size of grape seeds , there were also a few submucosal hæmorrhages From Nov 18 onwards ten daily doses of 140 r were given to the bladder, the pain and frequency began slowly to improve, and the man was discharged convalescent on Dec 16 By the middle *of January micturition was normal and the enlarged glands* had disappeared On Feb 13 cystoscopy showed a normal bladder, and the patient felt completely restored to his usual good health

My thanks are due to Major R Bodley Scott and Mr Kenneth Walker for permission to publish this note

STAPHYLOCOCCAL OSTEOMYELITIS OF THE SPINE

BY

E C B Butler,
M B LOND , F R C S
ASSISTANT SURGEON TO THE LONDON HOSPITAL ,
SURGEON, E M S

I N Blusger,
F R C S
SURGEON, E M S , AND

Kenneth M A Perry,
M D CAMB , M R C P
PHYSICIAN, E M S

Staphylococcal osteomyelitis of the spine has been fully described by Wilenski (1934), Kulowski (1936) and Turner (1938) It may be divided into three main clinical types The first as a rule occurs in children or young adults and is characterised by a sudden onset with the symptoms of a severe bacteræmia The local signs are often subordinated to those of the general infection and the diagnosis is usually obscure, often only being made at necropsy Treatment in these cases is directed to combating the blood-stream infection, the patient rarely living long enough for the local treatment to become a problem During the last twenty years at the London Hospital 13 cases of this type were admitted and every one of them died Necropsy was performed on all of them and death was shown in every case to be due to bacteræmia with abscesses in the lungs and other viscera A correct diagnosis was made during life in only 4 instances, the remainder being labelled retention of urine, appendicitis, acute abdomen and cellulitis of the neck , 3 were treated as pneumonia

The second type has been ably described by Stammers (1938) The onset is sudden with general malaise and pain in the back An abscess rapidly forms, which may either point externally or form an intraspinal extradural collection, in which case signs of pressure on the cord become evident and meningitis may supervene later with fatal results Drainage of the abscess after laminectomy is probably the best line of treatment in these cases Stammers reported 3, of whom 1 died We found 2 fatal cases in the London Hospital records, both of whom died from a terminal meningitis

The third type is sufficiently rare to make it worth while publishing the following case, especially in view of the fact that the patient had the benefit of treatment with sulphathiazole

CASE-HISTORY

On Dec 15, 1939, a man aged 53 was admitted with the following history Three months before admission he had complained of general malaise with pains all over the body His wife had noticed that he developed an angular deformity of his spine He had had persistent fever and had lost 3 st in weight Recently he had complained of a band like pain around his chest He was an ill, wasted man, weighing 7 st 6 lb Temperature 100° F , pulse rate 108 , respirations 24 There was an angular deformity at the level of the 5th thoracic vertebra His fingers were slightly clubbed The mediastinum was not *displaced* There was diminution of movement, dullness and absent breath sounds at the right base A provisional diagnosis of carcinoma of the lung with secondary deposits in the spine was made *Radiography* showed complete collapse of the 5th and partial collapse of the 6th dorsal vertebræ There was an opacity spreading downwards and outwards from this re
to be a retropleural abscess

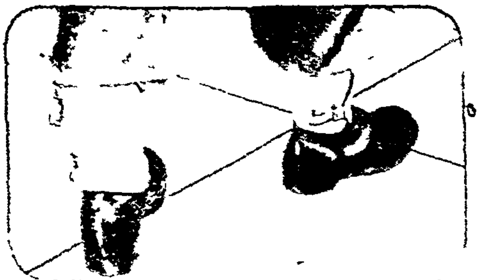
Increased incidence of minor wounds

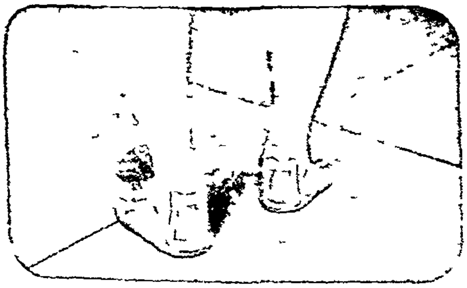
The incapacitation often resulting from sore heels and toes can be averted by the application of an 'Elastoplast' Dressing 'Elastoplast' Wound Dressings comprise an antiseptic pad of gauze medicated with Bismuth Subgallate on the elastic adhesive 'Elastoplast' base

For N H I prescriptions, these dressings, medicated with boric acid, are available in the four specified sizes

The 'Elastoplast' Doctor's set contains 106 'Elastoplast' Dressings in various sizes, and is available through your usual surgical supplier at 8/6d.



'Elastoplast' Dressings applied to the heel and other tender parts of the foot prevent blisters



'Elastoplast' Dressings will not ruck up or become displaced in wear

of tuberculosis He told how one large firm claimed to have saved considerable sums by X raying its staff and their relatives periodically The miniature method, while perhaps not quite as good as full-size X rays, is superior to screening

SIR WILSON JAMESON said that mass radiography offers the only method of the future for improving early diagnosis but he pointed out that difficulties may be encountered in persuading men to accept the sharp drop in standard of living between their wages and national health-insurance benefit

The discussion was continued by Dr S COCHRANE SHANKS who stressed the importance of speed in the technique of miniature radiography for large groups, and the CHAIRMAN warned the meeting that we must expect a halt in the improvement of tuberculosis in the country for some time to come owing to the reduced standard of living and the housing shortage which he feared would accompany and follow the war

Reviews of Books

Man on his Nature

The Gifford Lectures By SIR CHARLES SHERRINGTON, O M London Cambridge University Press Pp 413 21*s*

MODERN use of the experimental method in science dates from the Renaissance, yet since inductive reasoning gave place to the more workaday hobby of collecting and studying facts the mind of man has made an astonishing journey Sir Charles Sherrington establishes the contrast by setting out first the scientific standpoint of Jean Fernel, the sixteenth century physician to Henry II of France, who represents the best opinion of his day, and compares his conclusions (not his intelligence or judgment) with those we can form today on the basis of greatly increased factual knowledge Where Fernel distinguished living and non-living we can speak of energy composed ultimately of identical units, in our world such units are linked to form systems which achieve a temporary equilibrium In the living cell Sherrington shows us this equilibrium as a foaming, stirring physicochemical state constantly changing and as constantly restoring itself In non-living matter the difference is of degree not of kind, the physicochemical equilibrium is still impermanent and unstable, but its changes are less violent and swift, the table is less ephemeral than the professor who leans on it The living is thus no longer cleanly distinguishable from the non-living, in a world composed of energy we find ourselves able to study different manifestations of energy, that is all Our ancestry, too, is humbler than Fernel supposed, and the origins of life lie not in a moment of sublime creation but in the physicochemical adventures at surfaces of vapours, fluids and solids in a cooling world, though here we are extending knowledge to the length of a reasonable guess Many things which Fernel, lacking data, misinterpreted we can now measure and check as manifestations of energy One still eludes us—mind Conscious thought is not energy It provokes no measurable changes in any part of us, and we even lack any sense-organ by which to observe it We can hazard no guess on the nature of mind because here we still lack data We cannot even say certainly at what level in the animal scale it appears, some observers claim that even the one-celled animal is capable of learning by experience Sherrington would have us accept energy and mind as a working biological unity, although we cannot describe the how of that unity

"An individual organism with recognisable mind is a space-time system which the energy concept because of that mind fails to cover fully In such an instance the two concepts prove to be complemental our being is a unity whose behaviour we can follow only by including the two concepts and treating them as having 'contact utile' with each other" On this basis we can study them, experience shows, fairly Conscious mind is of recent origin, a humble affair as yet "man is awake and does and sees," but drowsily still The nature of conscious mind and the relation of mind and brain are of acute practical importance to the neurologist and the psychiatrist Until they are established conclusions in both fields must be tentative and empiric, and science expects caution when theories are formulated or announced We can at least be sure that brain and mind have developed together "Between the individual human mind and the individual human forebrain considered in time and space there is 100 per cent correlation"

"Man on his Nature" is too rich in knowledge, too profoundly stirring to the wits to be discussed relevantly in a few brief paragraphs No single message emerges from a book which like a ripe carpus is crammed with new thoughts in seed But one magnificent certainty is pressed home, it is of the nature of living things to grow, willy-nilly Our circumstances have made us, and at last have made conscious mind If it were not useful to our survival we should not have it and we cannot stop it becoming We can look with hope towards the mind of man to come as being suprahuman (as we know human) and thus, perhaps, more keenly aware of the "values" which conscious mind discovers "His oncoming had been an outstripping of other minds His dominance pillars on mind Will that ensure its future?"

Microscopic Anatomy of Vertebrates

(2nd ed) By JAMES I KENDALL, D Sc, assistant professor in biology in the City College, New York London Henry Kimpton Pp 342 17*s* 6*d*

FEW handbooks on comparative histology are available for the student and this work provides a sound and pleasantly presented introduction to the subject The different systems are taken in separate chapters after the manner of standard textbooks of histology, and in each the main anatomical and histological variations characteristic of the different classes of vertebrates are described It is a pity that all sections could not be as fully worked out as those on the integument and the digestive system, which are excellently done Unfortunately a textbook of this type has self-imposed limitations and the curious minded must seek elsewhere for the fuller details—Dr Kendall has provided a bibliography for this purpose A section on technique gives useful hints on fixation and section-cutting

Synopsis of Materia Medica, Toxicology and Pharmacology

By F R DAVISON, M B, M Sc, assistant professor of pharmacology, University of Arkansas London Henry Kimpton Pp 633 25*s*

BELIEVING that pharmacology is "an integral part of medicine," Dr Davison deals with it from the clinical viewpoint A therapeutic classification is adopted To the practitioner and senior student this will be an advantage, but for the junior student the arrangement has the drawback that information concerning many important drugs (e g mercury) is scattered through various sections But the beginner will welcome Dr Davison's introductory chapters on general principles of pharmacology, pharmaceutical preparations and processes, and prescription-writing The work is synoptic only in the sense that an attempt has been made to eliminate superfluous matter and the author has tried to keep an eye on the utility of the drugs included, there is a vast amount of information in its 600 pages of small type Phraseology is concise and the imperative mood is often used to achieve brevity, but historical notes serve to leaven the somewhat terse and prosaic presentation Students will appreciate the prescriptions incorporated in the therapeutic sections Many important chapters are prefaced by short physiological surveys, and Dr Davison's special knowledge of toxicology is reflected in his skilful correlation of this subject with the pharmacological and therapeutical parts of the text For the sake of the English reader, in future editions the lists of official drugs and preparations might perhaps include a selection from the British Pharmacopœia

Black's Medical Dictionary

(16th ed) By J D COMRIE, M D, F R C P E London A and C Black Pp 1006 20*s*

THIS "Special War Edition," as it is called, has been thoroughly revised Among much other fresh material it contains notes on the sulphanilamides and a supplement on the management of air-raid casualties including those caused by gas Notes on each subject are necessarily short, but they are simple and expressed in non-technical language Apparently at whim de

some cases but not in others

THE LANCET

LONDON SATURDAY, APRIL 12, 1941

TUBERCULOSIS AND WAR

AFTER the war of 1914–18 a well-known professor of medicine in Vienna remarked that it had been a colossal experiment in metabolism. Much the same might have been said about it in relation to tuberculosis. In both cases it was uncontrolled experiment vitiated by almost every kind of variable factor. It is too early yet to determine what effect the present totalitarian war will have on the tuberculosis mortality of Europe, but there is good reason to face what facts we have. Prof. E. L. COLLIS[1] describes how the resisting power of the population to tuberculosis was weakened by food shortage in the last war, especially in middle Europe. Mortality from all forms of tuberculosis had steadily diminished in the second half of last century, the decline being greatest at the beginning of life, smaller in early adult life, and least in more advanced life. During the years immediately preceding the war the rapid fall in early life continued, but it slowed down in the age-group 20–25, and quickened in the group 45–55. Then came the war, and the mortality steadily rose from 1914 to 1918. COLLIS considers that the disturbance of the male population by military service was so great that it is impossible to draw conclusions from figures relating to them and confines his remarks to the statistics for females. Analysing the figures in age groups, he points out that no change occurred in the first 5 years of life, but that, thereafter, until about the age 30, a steady percentage increase in mortality became manifest, growing as year succeeded year until 1918. From about 30 onwards to old age there was no increase. GREENWOOD has shown that this rise among females was directly proportional to their employment as munition workers; it did not happen in districts where munitions were not being made. Lastly in the age-group showing the war rise in mortality the rate of fall lagged in the years which followed the war; this lag was visible until the generation born after the war grew old enough to replace all members of that age-group. But the 1918 figures were disturbed by another factor—the influenza epidemic. This great pandemic followed the usual course, taking its heaviest toll of the older generation, until the last 8 days of June, when a high mortality suddenly appeared in the young adults—that is, in the age-groups upon which tuberculosis had been hammering harder and harder during the previous 4 years of war. This sudden alteration in mortality was unique. COLLIS quotes from a Ministry of Health report, "It may be doubted whether so sudden and so complete a change of age-incidence can be paralleled in the history of any other disease—yet all the weight of medical testimony goes to show that the influenza of 1918 was essentially the same as that of former years." He ends with the query, what is it reasonable to expect as 1939 passes to 194–?

Dr. FREDERICK HEAF and Dr. LLOYD RUSBY note that on Sept. 3, 1939, the tuberculosis service became seriously disorganised because of the anticipated blitzkrieg. Tuberculosis officers were chiefly concerned with A.R.P., many sanatoriums were converted into class 1 and 2 war hospitals, operative treatment was temporarily brought to a standstill (in some cases even before a many-staged procedure had been completed), care committee work largely ceased, the open-air schools were closed and the children billeted in the country, and hundreds of tuberculous persons—many of them in an infective state—were discharged from institutions to their homes. It is easy to be wise after the event; the best that can be said of an intolerable situation is that in our preoccupation with war and its new untold possibilities in the air we forgot our peace-time responsibilities to a large and infective class of the population. At the end of 1939 there were 70,000 sputum-positive cases on the dispensary registers, including 10,000 in London alone. In due course the position was taken in hand by the appointment of a standing advisory committee by the Ministry of Health, and 6000 beds were released. Meanwhile the dispensary services began to re-establish their organisation; by the summer of 1940 a "fair degree of normality" existed again. Then came the threat of invasion and the period of intensified bombing. There were many sanatorium beds in that restricted strip of land, 20 miles wide from Edinburgh to Bournemouth, which constituted the dangerous area, and a plan for evacuation had to be worked out, beginning with helpless stretcher cases and gradually extending to the ambulant patients. The bombing of London and the dispersal of known infective cases to the shelters produced yet more anxieties, and to those who know the difficulties which even in peace-time surround the chronic ambulant sputum-positive case these anxieties will occasion no surprise. Lastly there was the ebbing and flowing tide of evacuation from vulnerable areas with its attendant risks of the billeting of the tuberculous patient on healthy homes. What the future holds in store for the tuberculous patient, especially if rationing becomes more severe, none can say. HEAF and RUSBY take the view that the man living at home and unfit for work is going to feel more acutely than his fellows the stringency of rationing. But we started this war with certain advantages over August, 1914. Our tuberculosis mortality was lower, the number of available beds was greater, and the dispensary system much better equipped and operating throughout the country.

ASSAY OF ANALGESICS

IN the mind of the experienced practitioner certain pains are equated to particular analgesics; he would not offer aspirin to the patient "climbing the walls" with ureteric colic, nor resort to morphine to comfort the fat woman with fibrositis. Having selected the appropriate drug, the amount ordered is determined by a number of considerations, including the range recommended by the pharmacopœial commissioners, the size of the patient and the severity of the pain. The principles of posology have been worked out in considerable detail by pharmacologists, and for such remedies as diuretics, gastric antacids and antiseptics it is often possible to obtain independent evidence that these rules are accurate enough for clinical

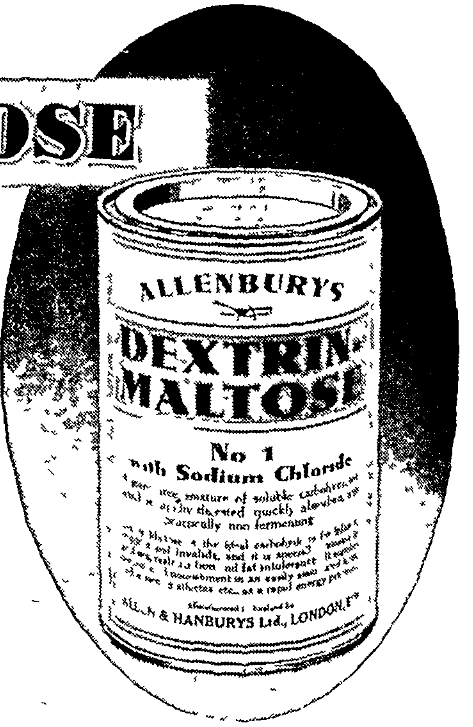
Allenburys
DEXTRIN-MALTOSE



THE use of Allenburys Dextrin-Maltose is indicated in digestive disorders of infants, children and adults

This mixture of carbohydrates is easily digested, resists fermentation, and counteracts tendencies to diarrhœa It makes milk more digestible

In six forms

- No 1 contains 2% of sodium chloride
- No 2 is free from addition of sodium chloride
- No 3 contains 3% of potassium bicarbonate
- No 4 contains 150 units of Vitamin D per oz
- No 5 contains iron and sodium chloride
- No 6 contains a prophylactic proportion of the anti-scorbutic Vitamin C equivalent to 5 mg of ascorbic acid per oz.

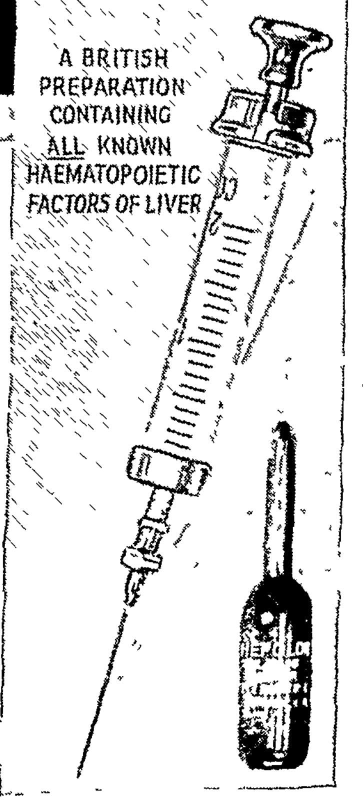
HEPOLON



A BRITISH PREPARATION CONTAINING ALL KNOWN HAEMATOPOIETIC FACTORS OF LIVER

TOTAL LIVER EXTRACT FOR PARENTERAL INJECTION

is produced by improved processes which conserve all the known hæmatopoietic principles of the whole liver, it gives no reactions for histamine or undesirable protein HEPOLON approximates to the extract described by Gansslen, later extracts have been described as of narrower therapeutic value

HEPOLON not only passes the highest clinical tests for potency against pernicious anæmia but contains Whipple s factor, Wills s factor, vitamin B_2 nicotinic acid, and the hæmatinic minerals of liver

Prices in Great Britain and Northern Ireland (subject to alteration without notice)

Ampoules of 2 c cm box of 6, 6/-, box of 12, 11/6, and box of 24, 22/-

Rubber-capped vial of 10 c cm, 5/-, and of 30 c cm, 12/6

ALLEN & HANBURYS LTD LONDON E 2

Telephone Bishopsgate 3201 (12 lines) *Telegraphic Address* Greenburys Beth London hyperemesis, nor is the theory of syncytial or endometrial embolism more convincing, since sickness is by no means a constant feature in cases of hydatidiform mole or chorion epithelioma, where the absorption of tissue cells from the uterus should be greater than in the normally pregnant. So-called toxic vomiting in most cases is the end-result of a long period of sickness that has been labelled neurotic in the first instance. Any vomiting from whatever cause if unrelieved for a sufficient time results in dehydration, metabolic changes and liver damage. It would therefore be well if the label "neurotic hyperemesis" were abolished, and if this was done many cases would never become toxic. Many a woman with hyperemesis has, owing to her physician's perseverance in his diagnosis and treatment of the case as one of neurosis, insensibly lapsed into a severe and irreparable state of toxicity. If all cases of severe vomiting were primarily treated as toxic and potentially dangerous valuable time would not be lost.

Since most cases of hyperemesis develop from persistence or exaggeration of the physiological early morning sickness or nausea of pregnancy, it behoves us to eliminate this early and thus make a prophylactic attack on hyperemesis. Simple remedies of diet and discipline will often suffice. The severer class of case demands immediate and more drastic treatment; it can be recognised by the dehydration, raised pulse-rate, depletion of urinary output, dry, furred tongue, sore mouth and sordes about the lips, ketosis, anxious facies, icterus, albuminuria, loss of weight, lowered blood-pressure, insomnia and mental symptoms. Any or several of these are grave phenomena and may suddenly develop in a woman who has merely been vomiting more persistently than usual. FAHMY relies on three essentials in the treatment of these severe cases: rest, fluids and bowel lavage. Rest he obtains by hospital or institutional treatment and the exhibition of bromides or Luminal; he does not advise morphine or opium, since they increase the dryness of mouth and tongue so distressing in these cases. Fluids must be pushed to the point of adequate hydration by the rectal or intravenous route, and it is important to be sparing with salt. To overstep the salt requirements in a dehydrated patient will only upset the intercellular metabolism and may lead to œdema of the lungs and embarrassment of an already toxic myocardium. Probably the best prescription for prolonged and heavy intravenous therapy is 5% glucose in 1/5 normal saline as advocated by AVERY JONES and NAUNTON MORGAN.[2] Colonic lavage must be used intelligently and sparingly in the severer cases, since its empirical advantages may well be offset unfavourably by the disturbance that an over-enthusiastic cleansing of the bowel causes to an already exhausted patient. The question of when and if to terminate the pregnancy can best be answered by the clinical judgment of the obstetrician. If, after a short period of trial of rest and hydration (at most a few days), the patient is no better, it is justifiable to empty the uterus. If done betimes the operation is relatively safe; later it is not only harmful but useless.

On Monday afternoon Sir CHARLES WILSON was elected to succeed Sir Robert Hutchison as president of the Royal College of Physicians of London.

Annotations

ST THOMAS'S IN THE COUNTRY

APRIL 16 promises to become one of the most important dates in the history of St Thomas's Hospital, for on that day its branch hospital in Surrey will come into existence. Although to the casual passer-by the structure on the Albert Embankment may not seem unduly bomb-shaken, its utility as an efficient hospital has been so reduced that the governors, having been informed that the damage to property, equipment and drugs lies in the region of £1,000,000, have decided that the only way in which the traditions and service of the hospital can be maintained is by opening an annexe in the country. For this purpose they have been fortunate in obtaining a hutted hospital which was erected by the military authorities. It is proposed to begin with 72 beds; this number will be quickly increased to 200 and after some time to 360 beds. The reason for this final delay is the necessity for using some of the huts, until more can be erected, for the accommodation of the medical, nursing and lay staff. From the beginning the new hospital will have all the facilities of a modern hospital, with laboratories and X-ray department. An ambulance service has been organised both in Surrey and in London to bring patients to the new hospital. All the members of the honorary staff who are not in one of the Services will have beds in the new hospital and, as our advertisement columns have shown recently, arrangements have been made for registrars and house men. The curriculum of the medical school is being altered to come into line with the new hospital and the first batch of clerks and dressers are starting there at the beginning of the summer term. This move does not mean that the hospital in Lambeth Palace Road is being deserted. Ever since the evacuation of the hospital in September last year full outpatient facilities have been maintained and these will be continued on almost the same lines as in peace-time—incidentally, the outpatient attendances have been steadily mounting during the winter and spring. In addition, the present two wards will be maintained for civilian acute cases, whether medical or surgical, and air-raid casualties, as well as the small obstetrical unit which has been kept fully occupied ever since the hospital was evacuated.

In 1862, on the occasion of the opening of the temporary premises for St Thomas's in Surrey Gardens, we expressed ourselves as follows:

> The gardens, extending over more than twelve acres, have been carefully restored, and will present a feature novel amongst metropolitan hospitals. The student will here, in modern academic groves, pursue his studies in a little oasis of quiet and beauty, including every appliance for health, comfort, and relaxation, situated in the centre of an enormous population, such as can alone require a large hospital and supply the elements of medical, surgical, and obstetrical education. The patients themselves will enjoy the advantages of free air, repose, pleasant prospects, and exercise to an extent unknown in other London hospitals. The situation and capabilities of the place are felt to be so excellent that the eccentric idea of building St Thomas's on some distant rural spot must be abandoned.

Alas, what seemed so desirable a site in 1862 is not ideal now, and many of us are wondering whether the present move indicates at long last a break in the peculiar English tradition that patients should be nursed in the midst of some of our most squalid and over-populated districts rather than in the open country.

SYMPTOMS OF THREADWORMS

THE finding of threadworms in the stools of children is often too readily accepted as an explanation of vague disturbances in health. To get over this difficulty in their investigation into the symptomatology of threadworm infection T. H. Weller and C. W. Sorenson[1] chose purposes. The position with analgesics is different, for until recently we have had no means of measuring pain, and this has delayed the advent of accurate knowledge, particularly with reference to optimum dosage. Thus it has perhaps been too readily assumed that within toxicological limits analgesic potency is directly proportional to the size of the dose. Recent work seems to show that this simple linear conception of the relationship is erroneous and that an asymptote represents the true state of affairs.

[2] Jones, F. A. and Morgan, C. N. *Lancet*, 1939, 2, 611.

[1] *New Engl. J. Med.* Jan. 23, 1941, p. 143.

WOLFF, HARDY and GOODELL of Cornell have extended their work on the measurement of pain and the pain threshold-raising action of the opiates[1] by making similar investigations on the commoner non-opiate analgesics, including aspirin, phenacetin and amidopyrin.[2] As before, pain was produced by a 1000-watt lamp, controlled by a rheostat, focused on the subject's forehead. They find that the minimal effective dose of aspirin as an analgesic is 0.9 mg. per kg./body-weight (about gr. 1 for a patient of 60 kilos). The smallest amount that produces the greatest threshold-raising effect is 0.3 g. (gr. 5). If the dose is increased beyond gr. 5 the rate of excretion rises so rapidly that the higher doses give comparatively little prolongation of analgesic action. Thus aspirin gr. 5 produced analgesia for 4½ hours, and six times this dose prolonged the effect by little more than an hour. Various combinations of analgesics were studied, including the well-known A.P.C. powder, and it was found that the threshold-raising effect of these compound powders was no greater than that of their most effective ingredient. As far as analgesics are concerned, then, the time-honoured custom of prescribing basis and adjuvans seems to be seriously threatened. On the other hand, it was noted that the sedative and hypnotic side-effects of these combinations of drugs were summative. Ethyl alcohol in doses of 30–60 c.cm. (½–1 oz.) has a threshold-raising effect rather greater than that of aspirin; here again, the larger doses do not increase the intensity of the effect though their action is more prolonged. This remarkable advantage of alcohol over aspirin revealed by the time-action curve is worthy of note by pharmacologists who, in the laboratory at any rate, have scarcely done justice to the virtues of a double whisky. The mechanism of the analgesic action of alcohol is confirmed and clarified by these investigations, for the subjects tested experienced feelings of contentment and detachment. This emotional state resembled that produced by opiates and resulted in "an ability to dissociate pain perception from the pattern of reaction to pain." In their previous researches on the opiate analgesics, these workers found that the potency of morphine and its derivatives in raising the pain threshold was considerably diminished by the presence of another uniform painful stimulus—produced by a sphygmomanometer cuff kept on the arm at 220 mm. Hg for 40 min. By contrast, the antagonism between pain and threshold-raising action is slight or absent in the case of aspirin, phenacetin, acetanilide and ethyl alcohol. Amidopyrin, phenacetin and acetanilide are often thought to be more potent analgesics than aspirin, but the impression is not confirmed by this investigation; apparently there is little to choose between them, whether we consider threshold-raising power or duration of analgesia. There seems therefore to be little justification for using these drugs, for it cannot be claimed that any of them have additional therapeutic effects which make them indispensable. On the contrary, their toxicity is such that the use of acetanilide no longer receives official sanction and amidopyrin has been largely removed from proprietary remedies because of its liability to lead to agranulocytosis. Even phenacetin, though harmless in therapeutic doses, should be employed cautiously in view of its relationship to acetanilide. Compared with these compounds aspirin has only low toxicity, and in the light of the present findings it may reasonably be regarded as the best universal analgesic that has yet been evolved.

This work reveals more clearly than ever the gap that exists between the synthetic analgesics and morphine. An analgesic as effective as morphine but lacking the unpleasant side-effects and complications which often attend its prolonged use has yet to be found. Some proprietary remedies purport to fulfil these requirements, but most of these claims are discredited by the most casual examination of the list of ingredients, and the others can now be tested by the technique of WOLFF and his colleagues. New analgesics are urgently needed, and this accurate method of assessing their potency should stimulate collaboration between the clinical pharmacologist and the synthetic chemist. These new methods for the quantitative investigation of pain may also find applications in other fields of research. Thus the observation made at Cornell that ergotamine tartrate has no effect on the pain threshold, though a negative finding, is none the less valuable as a contribution to the elucidation of the action of this drug in migraine. Again, in the realm of psychiatry, there is plenty of scope for the study of pain and analgesia among patients suffering from psychoneurosis.

HYPEREMESIS GRAVIDARUM

OF cases of excessive vomiting in pregnancy only a proportion can fairly be classed as hyperemesis, and some strict clinical criterion would be a help in assessing changes in incidence and prognosis. Quoting the figures for the last seventeen years from the Royal Infirmary, Edinburgh, FAHMY[1] notes that in the first seven years there were 22 deaths in 206 cases, while in the last ten years there were 17 deaths in 603 cases, a fall in fatality from 10.6 to 2.8%. From these figures it seems that with readier admission of these cases to hospital severe hyperemesis is decreasing. FAHMY discounts an element of neurosis in the ætiology for the following reasons: most women desire their pregnancy, yet 40–50% suffer from some degree of vomiting; whereas many unwanted pregnancies are not associated with vomiting at all, nor is the condition relatively more common in pregnancy in unmarried women. Moreover, the average pregnant woman is not predisposed to neurosis, and in a considerable number of cases vomiting precedes certain knowledge of conception. Neurosis may exaggerate but cannot initiate the vomiting. Equally flimsy is the evidence for the toxic theory, since many of the toxic manifestations are the effect rather than the cause of as shown that much larger doses for 28 days had no ffect on the kind, incidence or duration of scarlatinal omplications Better results are obtained if the drug s used curatively at the onset of septic complications, nd toxic reactions are thereby greatly diminished ulphanilamide is recommended for meningococcal eningitis, whereas present practice here is to use, paricularly with severe infections, sulphathiazole or sulpharidine by mouth, or intravenously if the patient annot swallow Contrary to their statement, the oluble sodium salts of these drugs can safely be given ntravenously along with saline or glucose, although, ith the tendency to precipitate out, it is less safe to dd them to plasma or blood Sulphathiazole is recommended as the treatment of choice for lobar pneumonia ; hemotherapy is much less effective in secondary bronchopneumonia Specific antipneumococcal serum is recommended as additional treatment only in certain special circumstances—a remarkable volte face in America Surprisingly, scarlatinal antitoxin is to be given in septic scarlet fever, although American clinicians claim much better results from immuno-transfusions in such cases Antitoxin is not mentioned in the treatment of staphylococcal infections Although serum is given pride of place as supporting treatment in the prevention and treatment of gas gangrene, the statement that sulphanilamide given prophylactically almost always eliminates the possibility of gas-bacillus infection is without any reliable clinical backing

These differences of viewpoint serve only to emphasise the wide field covered in this circular letter and to show the value of such practical advice as it contains A pamphlet on similar lines drawn up by, say, a committee of the fevers group of the Society of Medical Officers of Health and circulated to all infectious diseases hospitals would fill a widely felt need

PERITONEAL FLUID AS AN AID TO DIAGNOSIS

FACED with an acute abdomen, the surgeon of today is still without real help from any of the newer sciences and he must rely almost entirely on his clinical sense What may be called the laboratory lag makes the clinical pathologist inaccessible, and, even if the radiologist can sometimes help, the decision to act—be it in typhoid fever, appendicitis or in intestinal obstruction—must be an immediate one A method to make laboratory aid less tardy is proposed by Steinberg,[1] who has studied the pathological peritoneal fluids in over 150 cases of inflammation or irritation Much is already known from experiments about the cytological response of the peritoneum to bacterial and other irritants, but Steinberg is concerned with peritoneal exudates as a guide to the diagnosis and prognosis of intra-abdominal conditions Peritoneal fluids were removed by abdominal puncture, at operation or at autopsy shortly after death, and records were kept of the numbers and type of organisms and cells, of cell structure, of the number of leucocytes with ingested bacteria, and of the presence of extraneous substances in the fluids in different conditions and at various stages of their development Thus the fluid in early infections of the peritoneum shows about 8% of mesothelial cells, 90% of polymorphonuclears and 0–6 bacteria free in an average oil immersion field , while in late infections the exfoliated mesothelial cells may rise to 20%, intact polymorphs may be present only in moderate numbers, and the free bacteria may rise from 10 to uncountable numbers in a smear Whatever the value of such tables to the skilled interpreter it is better for most of us to place trust only in the grosser features which may make diagnosis certain The finding of a specific pathogen such as the pneumococcus in the fluid, the presence of numerous intestinal species of bacteria in appendical peritonitis, the mucinous material and fibre strands in peptic-ulcer perforation and the cholesterol crystals in bile peritonitis are of immediate help Steinberg suggests that the fluid may be obtained from the mid abdomen by puncture with an ordinary needle and syringe or by a special capillary pipette before operation or immediately the peritoneum is incised , and that microscopic examination of the fluid in stained smear and wet preparations should be made on the spot The occasions on which this sort of pathological support for the surgeon may be possible are not very numerous but there are times when abdominal puncture might certainly help—for example after operation when the decision is between distension caused by atony or by infection , or before operation when salpingitis, appendicitis or ectopic gestation may all be under consideration The dangers of the exploratory needle are probably not great, as those familiar with animal experiments know, and the operation has often been performed on children without unhappy complications One point emphasised by Steinberg is that the fluid must be withdrawn from the mid-abdomen but he has yet to show that the fluid from this area adequately represents or even indicates conditions in other parts of the peritoneal cavity

CALCIUM AND IRON

STEPS are being taken to make good any lack of calcium that there may be in our food by the enrichment of white flour with chalk, and there is ample evidence that calcium salts supplied in this way can be utilised by man Nutrition, however, is a complex matter, and one constituent of the diet cannot be altered without a risk of upsetting the utilisation of some if not all of the others Recent work by Kletzien[1] and Tompsett[2] has indicated that the addition of large amounts of calcium-containing substances to the food of mice and rats interferes with the absorption of iron and reduces the iron stores of the body This observation is interesting from two points of view In the first place it throws some light on the complex factors regulating mineral metabolism Tompsett suggests that calcium acting in the intestine as a base lowers the acidity of the intestinal contents and as a result lessens the solubility of iron salts and the proportion present in the divalent or ferrous state It is held by some workers that the reaction of the intestinal contents plays a leading part in regulating the amount of mineral absorbed At the same time it must be remembered that patients with achlorhydria do not necessarily suffer from anæmia Hutchison,[3] indeed, has shown that the actual absorption of iron in an achlorhydric subject was not impaired The retention of calcium itself does not appear to be significantly affected by the administration of a diet rich in alkali[4] The question arises whether calcium exerts a specific action on absorption apart from its tendency to produce an alkaline reaction in the upper intestine Certainly a high calcium diet greatly reduces the absorption of lead The possibility that lime salts in large amount affect the secretory or absorptive powers of the intestinal epithelium should not be entirely disregarded, for in addition to its actions as a bone builder and regulator of neuromuscular excitability calcium seems to play an important part in controlling the distribution of water between cells and tissue fluids Of more immediate importance is the question whether the addition of chalk to our bread will have a deleterious effect on the synthesis of hæmoglobin by limiting the absorption of iron It would be a national disservice to exaggerate the possible dangers of this dietetic adjustment, and as has been pointed out in *Nature*[5] the maximal increase

387 consecutive outpatients at the Children's Hospital, Boston, none of whom had been brought to hospital because of a primary complaint of threadworms An arbitrary list of eleven of the signs and symptoms most often ascribed to threadworm infection was selected for study These fell into three groups First came gastro-intestinal symptoms, including nausea and vomiting, vague intestinal pain, diarrhœa, loss of weight and loss of appetite Next came certain local, perinæal symptoms —anal pruritus, anal skin lesions, and vaginitis and vulvitis Finally there were three nervous symptoms—night restlessness, enuresis and masturbation Each of the children was subjected to a special examination by the "N I H swab," an anal swab consisting of a portion of Cellophane folded on a small glass rod and widely used for the accurate determination of threadworm infection in the United States A group of 118 inpatient children were also examined by the anal swab Of the 505 children, 97 (19%) were found to have threadworms, more girls being infected than boys Of the outpatient group, in whom the special study of symptomatology was made, 72 (19%) had threadworms and 315 (81%) were free It was found by comparing these two groups that children with threadworms complained of gastro-intestinal symptoms no more often than the uninfected children, with the exception of a slightly greater percentage showing loss of appetite—a finding at variance with the popular idea that "worms" produce an abnormally large appetite The incidence of vulvitis and nocturnal restlessness was the same in both groups of children The remaining symptoms—anal pruritus, anal skin lesions, enuresis and masturbation—were slightly commoner in the positive group but in no case was the variation statistically significant This study does not, of course, give a fair picture of the symptomatology of threadworm infection since it deliberately excludes children who were known to have worms in the stools But it does reveal the relatively frequent occurrence of latent or what may be termed "subclinical" infection Of the 72 positive swab children 64% had no gastro-intestinal symptoms, 80% had no perinæal symptoms and 58% had no nervous symptoms Actually 36% had none of the eleven symptoms chosen for inquiry These findings must not be interpreted as meaning that threadworm infection causes no symptoms, but in the past the symptoms attributed to threadworms have been so vague that they could probably be elicited from a large proportion of the normal population More study is needed to tell us why some patients have symptoms and some not Meanwhile it is a disquieting thought that nearly 1 in 5 of the white children attending the Boston Children's Hospital are harbouring these worms without their parents' knowledge

THE SIGNIFICANCE OF CERVICAL METAPLASIA

THE very early diagnosis of cervical cancer offers a problem which has often perplexed the pathologist and confounded the surgeon At one time it was not uncommon to regard the cervix as precancerous, or in an early stage of actual cancer, if it was the seat of epithelial metaplasia, but experience of the action of gonadal hormones on the uterus and vagina in animals has changed our opinions Carmichael and Jeaffreson [1] point out that in the cervix of the healthy nulliparous woman the stratified epithelium of the vagina abruptly gives place at the margin of the external os uteri to the columnar celled lining of the cervical canal, and there is no intermingling of one type of epithelium with the other Often, however, a stratified, non secreting epithelium, sometimes surmounted by mucus containing cells, is found within the cervical canal, it may be in isolated patches and occasionally extends deeply into the cervical glands, thus in some degree simulating early cancer Carmichael and Jeaffreson have studied the condition by a histological survey of 400 human cervices They find no evidence to support the old contention that the stratified epithelium has spread by a direct ingrowth from the vaginal face of the cervix, its presence in the cervical canal is in fact the result of a local metaplasia Among the cases which provided the material for their paper endocervical metaplasia was present in 35% of women under fifty and in 50% of those over fifty, otherwise the influence of age was slight No evidence was found suggesting that inflammation plays an important part in causing the lesions, nor that the changes are precancerous They suggest that the condition may be induced by sex hormones acting in conjunction with local causes Such a view is in accord with experimental results obtained with sex hormones in animals, these have shown that œstrogens cause stratification of the vaginal epithelium, and—if given in sufficient quantity—of the cervical endothelium too Susceptibility to this reaction is innate in the cells, and is graded in degree so that an amount of hormone enough to cause stratification in the vagina will not necessarily cause a like change in the cervical epithelium, though larger doses, if given long enough, will have this effect The boundaries of these gradients of susceptibility are not always precise, large doses of an œstrogen may provoke reactions which are not always well defined anatomically or evenly distributed Moreover, some hormones reinforce each other and others are antagonistic so that a given lesion cannot be attributed to a deficiency or excess of any particular hormone until the quantities of other effective hormones present at the same time have been estimated Finally, in the spayed rat mere irritation of the vagina, as caused, for example, by daily scraping, favours the appearance of epithelial stratification With such an experimental background the observations and microphotographs of Carmichael and Jeaffreson seem to agree

CHEMOTHERAPY IN AMERICA

THE American National Research Council evidently takes a realistic view of its functions Two of its committees—one on chemotherapeutic and other agents (chairman, Perrin H Long) and the other on infectious diseases (chairman, Francis G Blake)—have jointly issued a circular letter [1] on chemotherapy for infectious diseases and other infections Although they admit that it is impracticable, except in a broad way, to delineate therapy for persons suffering from various infections, they give specific advice about choice and dosage of sulphonamide drug and the indications for the use of specific antisera in the following diseases hæmolytic streptococcal infections (tonsillitis, otitis media, cellulitis, erysipelas, septicæmia, &c), scarlet fever and its complications, meningococcal and other purulent forms of meningitis, primary and secondary pneumonia, gas-bacillus infections and staphylococcal infections The various toxic manifestations from the three commonly used drugs—sulphanilamide, sulphapyridine and sulphathiazole—are listed and advice given about their prevention and treatment Not all the recommendations about use and dosage of drug would find general acceptance here For example, despite the risk of relapse, it is not customary to continue dosage in streptococcal or meningococcal infections at the rate of 6 g daily for 5–7 days after the temperature has subsided, as advised in this letter On the other hand, no instructions are given to the practitioner about when to stop the drug in cases which do not respond Opinion here is divided about the value of sulphanilamide in tonsillitis, and its use, as recommended, in 0 5 g doses four times daily for the period of isolation to prevent the septic complications of scarlet fever is not likely to be beneficial in fever hospital practice, where French [2]

STUDENTS IN CONFERENCE

Last year some six hundred students attended the meeting of the National Union of Students at Leeds, this year a thousand were expected at Cambridge and over eleven hundred arrived Many of them, using well the opportunity of war, came as hitch-hikers on cars and lorries, on April 1 they were converging on Cambridge through the rain some as hooded figures with mackintoshes and stout shoes, rucksacks on back, and some from farther afield wearing the kilt and the skiandhu Of this company two or three hundred were medical students members of the British Medical Students' Association, the northern universities were well represented in this group but members from the south were relatively scanty those from the London medical schools being disappointingly few, though the London School of Medicine made a good showing and contributed to the executive staff Students always make an impressive audience to their elders because they show that altruism which later experiences seldom leave undulled They have the generosity which might build a new world, if the world into which they are about to step was not geared to destroy that very quality This may account for the impatience with which one or two of their lecturers summed up at the end of discussions it is never very comfortable to meet one's former ideals face to face after twenty years of compromise The students were idealistic, yes, impractical, yes—even at times woolly But they have it seems, a keen social conscience, an anxiety to learn preventive medicine, to change those industrial conditions now injuring the health of their fellows and to turn medicine from a routine of patching up to something more constructive And this great head of energy, this weight of goodwill, is only ineffective because we have arranged our society in such a way that it is not harnessed The students are eager enough to put it into commission, nothing showed this more than their attention to Dr H G Stead, director of education at Chesterfield Technical College, Sheffield and the way in which they quoted him in the sessions that followed The idea which had caught them was one he introduced in speaking of the escapist device of responding "in the future" to a challenge which is immediate—the belief, for example that by doing something to improve the education of school-children we were relieved the responsibility of doing something constructive ourselves He suggested a concrete plan by which students might make a contribution now to the study of their times, approaching it by way of discussion of the public schools, these, he said, were established to train people for leadership at a time when political power was in the hands of the few and the main economic was agriculture Was their function still *desirable ?* Yes, in his view. But power had moved into more hands and the main economic was now industry. Only by drawing pupils from the whole people and by changes in the curriculum to meet the new economic could the public schools continue to fulfil the function for which they were set up He suggested that students might form small groups to study the curriculum of any school they knew, and to find out how that curriculum came into being, what purpose it fulfilled then, whether that purpose was still valuable and if so what changes were needed to make the curriculum fulfil the same function today.

THE CURRICULUM

Perhaps in no form of education is research so much needed as in the curriculum of the medical student Prof F. Wood Jones, who addressed the B M S A on the present position of medical teaching, gave his audience some excellent starting points for investigations of the kind In the days of the private medical schools, he said, students had to know enough botany to spot plants used in the British Pharmacopœia a smattering of zoology relating to the animals whose products appeared in the same work, and the chemistry of the drugs they used Their study of anatomy was nearly as full as it is today, but their physiology course was trivial When Huxley laid down the modern university curriculum in London scientists believed in uniserial evolution; as a result, the curriculum was loaded with all sorts of plants and pollywogs which were dead ends of evolution and threw no light on human structure It was topsy-turvy, indeed, to dissect a rabbit in preparation for the study of man man was the simplest mammalian type, it would be logical to give the zoologist about to study mammals a man to dissect before he passed on to more highly modified creatures Professor Wood Jones suggested that the first-year course might be replaced by what Americans called an orientation course—a general course in biology This should be given by the best and most mature teacher, his business being to provide an introduction to the study of life for the man who was going to deal with living organisms In the teaching of anatomy and physiology the study of structure must be related again to that of function The spinal tracts and the neuromuscular mechanism for example, must be taught together At present two bogies hanging over the internal teacher were the General Medical Council and the external examiner The G M C laid down the curriculum, but the students must somehow get a say in choosing that curriculum They were all registered with the G M.C ; students in Australia had felt that they were not getting much return for registration, and nowadays no-one in Australia registered

These stirring words on the curriculum provoked a flood of corroborative reminiscence from his hearers At one university, it seems, psychology is taught in a course of six lectures, delivered by a teacher who is not a psychologist One speaker began his address with the uncompromising statement "In —— our greatest curse is bad teachers" He said that of ten lectures a week (compulsorily attended two weeks out of three) it was agreed among the students that four were worth going to, and six were valueless He pleaded for a voluntary lecture system, teachers who were poorly attended might then improve their technique A Scottish speaker made a sound point when he said that in general practice minor gynæcological ailments were common, yet on gynæcology his university offered only ten lectures and ten theatres in the whole medical course Students, however, did clinical surgery for four terms and attended fifty lectures on operative surgery, how often would that stand the general practitioner in good stead ? Many appealed for a course which would bear more relation to the needs of general practice for a chance to see common and trivial ailments and—again and again—for better grounding in preventive medicine One pointed out that in spite of the lengthening course in chemistry they were taught nothing about industrial poisons At one medical school the students' union had studied their own criticisms of the curriculum and had finally put recommendations before the staff committee These had been considered and many of them had been accepted Some of the set lectures had been replaced by seminar classes attended by not more than fifteen people, and the casualty and gynæcology courses had been improved All favoured teaching on discussional lines, though there is always a danger that the dullards will hold up progress in a small class This, however, applies equally to the system of set lectures, as one speaker pointed out, one of his lecturers, he said, read his notes through at dictation speed—and there were students who liked it In his own view, lectures should be an aperitif, whetting the appetite for reading

TEACHERS AND TAUGHT

There are evidently students and students and it is in the nature of meetings of this kind that the best and keenest should attend. Prof G I Boyd at a later session, responding to a speaker who appealed for a wider educational grounding in philosophy and literature, said he often found students impatient of the cultural aspects of even their own studies In part this is no doubt due to the haphazard manner in which medical students are at present selected, the training is only within reach of those who can afford it and few of them have a vocation Professor Boyd found that the 10–15% of dullards could bring down the standard of the whole year, and mentioned with respect the motto of that Spanish university, which runs. "What nature has denied Salamanca cannot supply" He thought students might in lime produced by the addition of calcium to white flour is very much less than that used by Kletzien and Tompsett in their experiments There was an old view that excessive consumption of milk leads to anæmia, and if milk is taken to the exclusion of other foods this may well be true, not because of the high calcium content of milk but because of its very meagre content of iron The same may apply to the abnormal diets forced on us in war-time It will be wise, therefore, for the family doctor to make increasing use of his hæmoglobinometer just now, especially with expectant mothers and children, in whom the chances of iron deficiency are greatest

AUTOPSIES IN RURAL PRACTICE

HIMSELF a country practitioner, Dr W F Putnam[1] pleads for the routine performance of post mortem examinations in country practice and has contrived to get permission for, and to carry out, autopsies on 34 of the 64 of his patients who died in the years 1936–39 In most cases his clinical and pathological findings tallied tolerably well, though a clinical diagnosis of "stillbirth" is not greatly amplified by a pathological diagnosis of "stillbirth", autopsies ought to take us further than this *It is easy to be wise afterwards but it may be* wondered why some at least of the conditions first discovered at autopsy were not suspected before death It seems incredible, for example, that peritonitis due to a ruptured gall bladder should have been completely silent Nor should a thrombophlebitis have been missed, whereas a thoracic aneurysm might surely have been suspected and subsequently confirmed radiologically In so far as he wants us to perform autopsies to attain greater knowledge and accuracy Putnam carries us all with him It is only when he argues that, without the salutary cold douche of post-mortem evidence, country doctors are apt to become complacent and unconscious of their errors and limitations that some will want to join issue with him In this country the standard of country practice is at least as high as, if not higher than, that of towns and few if any rural patients die undiagnosed for lack of necessary special investigation One of the reasons why Putnam wants country doctors to carry out autopsies is to improve the standard of rural practice and so "eliminate the bogy of state medicine" It is difficult to follow his reasoning here A superstition widely held among those practising in towns is that country doctors enjoy a life of arcadian leisure whereas in fact one of the many difficulties of autopsy in country practice is to find the time and the place and the cadaver all together Post mortem examinations conducted on a trestle table in a freezing outhouse with a bucket of cold water as the sole amenity and the local Dogberry as assistant are toughening experiences which, though better than nothing, are not conducive to good and accurate work, where a post-mortem room, with a skilled pathologist hovering in the background is at hand, it is another pair of shoes Might not Putnam's dreaded bogy provide us with these ?

BURNS OF THE EYELIDS

How far coagulants must be held responsible for contractions following burns of the face or hands is still undecided, but the burns team of the M R C war-wounds committee have left no doubt of their own opinion, by their recommendation that no coagulant of any kind should be used on the face, hands and wrist, or feet[2] The voice of eye surgeons has been little heard in the discussions on this question, but certainly some of them maintain that eyes have been lost with tannic acid which might have been saved with other treatment In their view coagulants applied to the lids render them rigid, immobile and contracted, their protective function to the eye is lost, the cornea dries and ulcerates from exposure, and perforation and panophthalmitis will ultimately destroy the eye *Whatever his personal opinions,* no surgeon is likely to feel certain enough of them to ignore this warning, so that for the rest of the war coagulants are likely to be discarded in the treatment of burns involving the eyelids Careful diagnosis of the depth and extent of such burns is essential First degree burns merely require cleansing with saline or sodium bicarbonate, the application of saline packs and observation Those of second degree should be treated in the same way, with careful excision of all tags of dead epithelium and vesicles During observation it may become evident that some areas are in fact third degree In most burns of the eyelids the lid margins remain intact This is of great advantage in that it allows tarsorrhaphy to be performed, a procedure of vital importance for the *protection of the cornea and the prevention of ectropion* during healing or after the application of a Thiersch graft In third degree burns cleansing, excision of all devitalised tissue and tarsorrhaphy are followed by the application of a Thiersch or Wolfe graft, held securely in place by suturing the edges of the graft to adjacent skin and covering this with tulle gras and a piece of stent moulded to shape and held in position by sutures

ANÆSTHESIA FOR CHEST SURGERY

THE development of anæsthetic methods and technique to meet the full needs of the surgeon carrying out severe chest operations was discussed on April 4 by Dr M D Nosworthy at the section of anæsthetics of the Royal Society of Medicine He warmly advocated "controlled respiration," that system by which natural respiratory movement is suspended and the respiratory exchange is effected by rhythmic pressure on the breathing bag The advantage to the surgeon working within the chest of having the cavity free from movement needs no emphasis, and a safe technique to provide this may be acquired by experience Controlled respiration is obtained either by lowering the carbon dioxide tension or by heavy depression of the respiratory centre by drugs, to obtain it Dr Nosworthy uses cyclopropane at a percentage strength much above that considered safe in ordinary surgery He does not consider the use of Avertin or paraldehyde permissible to repress respiration because they abolish the cough reflex for too long For empyema and lung abscess local anæsthesia was recommended Cough must be prevented, because it disseminates infection, for this purpose either the infected zone of the lung must be shut off from the healthy parts or else suction must be used effectively Dr Nosworthy believes that the surgeon is well advised to forgo the advantage he might sometimes gain from the use of diathermy for the sake of using an anæsthetic whose inflammability must not be forgotten In civil life the subjects of severe chest surgery have generally suffered long-standing illness, often complicated by amyloid disease, and every possible step has to be taken to maintain circulatory and respiratory efficiency at the best possible level during operation In military chest surgery the position is different, the patient being, apart from his chest injury, a first class subject Dr C Langton Hewer considered the post operative fall in blood-pressure after cyclopropane to be due to the disturbance of metabolism produced by a sudden return from an atmosphere containing excessive oxygen

SIR COMYNS BERKELEY has been re elected chairman of the Central Midwives Board for the year ending March 31, 1942

In a circular (No 2323) addressed to local authorities and hospital boards the Minister of Health recognises the serious effect on private practice of the recruitment of practitioners of military age and suggests ways of allocating medical man power between the civilian and military services doubtful luxury of a paid companion There is a real need for superior almshouses especially for superannuated gentlefolk where for a reasonable payment they could have at least a bed-sitting room with the use of a communal dining-room recreation-room and garden with a resident nurse to attend to their minor ailments In such places they could husband out life's taper without the haunting fear of what is to happen to them if they should fall ill If I were a rich man it should be the first of my war-aims to build such refuges , it would be as “practical and limited ’ as the peripatetist's war-aim of a fixed retiring age, and is a necessary corollary to it

* * *

It has always been my lot to be associated in some way or other with zoological gardens no matter where I have been domiciled and people often ask me if I approve of keeping wild animals in captivity for public exhibition. At one time I was content with the answer that if scientific knowledge is gained in this way the business is quite legitimate but I have learned slowly that in the average zoo little scientific observation is carried out on the habits or life-histories of the inmates ; and that such as is done is so uncontrolled and uncoördinated as to render it almost useless I have sadly realised that little is added to real knowledge by the keeping in captivity of beautiful wild creatures and that many zoos are doing little better than providing wild beast shows for the entertainment of a public that should demand a more æsthetic introduction to nature In addition there comes the question of cruelty involved even in a wild beast show I have grown accustomed to a philosophy that for the powerful roaming animal captivity is undoubtedly irksome, unless the animal is bred of a long series of captive ancestors that has never known the wild I have a fancy that this thesis is defensible, despite the restless hunting urge that manifests itself even in the menagerie-bred carnivores But I have always thought I was on safe grounds in urging that for the many frightened little animals whose lives were ruled by dread and apprehension in the wild, the assurance of complete and assured safety compensated for the loss of liberty when in captivity This also I believe to be a thesis capable of common demonstration The assurance of food, of safety of shelter and of permanent residence under conditions as nearly ideal as human ingenuity can devise is a great compensation to a little timid, hunted animal whose wild life is spent in fear and apprehension.

In teaching students anything concerning the zoological position and the racial differentiation of man it has always been my aim to insist that civilised man is and has long been a domesticated animal Moreover, a large section of mankind is not only domesticated for the worker must also be regarded as an animal living in captivity Now to consider man as a domesticated animal is a helpful scientific concept, as anyone who has considered human racial differentiation in the light of Darwin's “Variation of Animals and Plants under Domestication” of 1868 must agree But to consider man as a captive animal is a more complex problem since it entails some knowledge of the social system under which he is held captive. If we accept the basal thesis that man, as a member of the primates, is a frightened animal in the wild we must face the question . “Has captivity diminished his fears ?” There is plenty of evidence on which such a question can be debated Natural wild living free man has his fears In certain places he fears wild beasts he fears the failure of his hunting he fears droughts and calamities of nature He fears the hostility of neighbouring tribes. But his fears are transitory They remain to be faced but their conquest is likely to create a return to the normal routine of life What of captive man ? His fear once he has taken upon himself the responsibility of the normal state of manhood, is fixed indelibly on him. His life is ruled by fear Fear of failure in his work. Fear of illness Fear of incapacitation. Fear lest those dependent on him are deprived of even the necessities of life while he is unable to earn a wage Under the system prevailing in our so-called civilised and Christian countries fear is the dominant note in the lives of all those men captive owing to our present social regime. It should not be beyond the imagination of the ordinary man to picture a state of affairs in which this ever-present and terrible load of fear is lifted in which the illness or incapacitation of the wage earner did not spell ruin to the family, in which man necessarily a captive in a world economic system yet had the protection the security and the assurance afforded to a timorous rodent in a zoological gardens It seems no very idealistic plea that man captive though he may be as a domesticated animal should yet have meted out to him the assurance that anxiety fear, dread of enemies and of shortage of food should be eliminated from his life as it is, for instance, in the life of a captive hamster There is surely an economic social regime that could accomplish this

* * *

Almost every practice has at least one Great Professional Sufferer whose agonies and tribulations surpass any previously recorded (‘Nobody can realise a thousandth part of what I endure) but whose heroic fortitude in spite of being misunderstood, in spite of lack of sympathy, snatches them time and again volubly from the grave (“My doctor says it is only my wonderful spirit that keeps me alive ’) Such a one was the writer of France Pastorelli's ‘ The Glorious Bondage of Illness ” (Allen and Unwin 2s 6d) She was a musician who is said to have developed an incurable form of heart disease, and to have been in bed for four years If the book goes to another edition—and I hope after all the lady will live to a ripe old age—a few clinical notes and an electrocardiogram would add interest for the medical reader I confess after reading the book I have not diagnosed the cardiac complaint.

There are two classes of great professional sufferer There is the humbug class who are G P.S.s because it pays them to be , it is the only way they can dominate their families or be important, or it is the most comfortable way of living I remember seeing about twenty of this last sort all together : it was not in this country, they were all soldiers alleged to have contracted tuberculosis in the Great War. Each had a chalet, was well fed and looked after, and enjoyed heroic status though few had heard a shot fired They had been there for ten years when I saw them and probably are there still Any suggestion that tuberculosis was a curable disease and of getting a move on was regarded as an *insult*, a brutal attempt to stop a comfortable career The other class is far more interesting , they are among those patients whom Nature wants to lie still *and so she has* given them a marvellous power of dramatising themselves and their surroundings A year ago I had a patient who lay like a log for three days with influenza. I asked him what he had been thinking about. He had imagined he was covered with invisible paint, and after various adventures in this country including an invisible interview with the P M he had gone into Germany and done some gloriously horrible things It was like a thrilling film and he was acting the principal part “Did you kill Hitler ? ” I asked “No I slipped into his bedroom and came over and stood by the side of his bed with my knife all covered with invisible paint, of course ready in my hand, I saw the vessels in his neck beating then he turned and looked at me, and with his moustache lying down and without his false teeth he looked so pathetic . ” Anyway *that fantasy* kept this young man quiet and amused for three days Some of Henley's manly verse and Stevenson's adventures are of this origin, healthy songs and stories *that Nature made them* tell themselves, which only incidentally came afterwards to us The first object of Keats's poetry was to keep him and his flaming lung quiet What a potent force this is which could make him see his crystal dreams sublime in an apothecary's shop or can for a little while at any rate transport every ailing exile home.

The second class of G.P.S s consist I think, of patients in whom this process is at work, but who haven't the imagination the visual imagery, to build a complete fantasy, and thus spoil it by mingling it with truth the sordid truth of illness and the sick room Madame *Pastorelli* probably belongs here and within these severe limitations she has written a book with some artistry. A healthy person's reaction to reading it will be impatience with the author and her “many Gethsemanes ’ , on no account should these chapters be put into the hands of a sick person, for, as the American girl said of the Ten Commandments, they just put nasty ideas in one's head well begin with a year of general training in sociology and philosophy, and take courses in nursing, industrial medicine and the relations of doctor and patient late in their course. He suggested, too, that they should have a year of "doing something else" between leaving school and going to the university. One of his realistic hearers agreed that we must improve the material entering medicine, but pointed out that we must also do the best we can with the material we have got. Back came the discussion, hammering away at the curriculum with warmth and good sense. Some were for appointing only trained teachers to teach, deprecating a system which compelled those whose hearts were in research to ladle out elementary knowledge; but some foresaw danger in such a change. Then indeed they might only be taught from potted textbooks, whereas the researcher, however dull his lectures, was established on the growing point of his own subject. As one speaker put it, the good researcher cannot talk badly about his work. It was agreed again that lectures should be fewer and more stimulating, demonstrations direct, and discussion between student and teacher free. Many deplored the gulf separating them from their teachers—even a literal gulf, at one university, where the teachers hurry home across a river, left nameless by the discretion of the speaker. For a few schools the war has helped to bridge the gulf. One of the evacuated London schools is housed in a country manor house, men, women and teachers together; a resident gave a thumbnail sketch of their communal life in which the men chop wood and clean bicycles, the women darn socks, and the teachers behave as men and brothers. One excellent suggestion was made for bridging the gap: that students and teachers should join in group research. This, perhaps, of the many changes suggested is the one which could be put most promptly in commission and which would be most likely to bring a good revolution in its train.

MEDICINE AND THE LAW

Damages against Chiropodist

A CHIROPODIST was ordered to pay £62 15*s* damages at Barnstaple county court last month on a claim alleging want of skill in treatment of the plaintiff's foot. Mrs. Colston, the plaintiff, said she had visited him for treatment for corns; but he had taken her foot in both hands and violently twisted and jerked it so that she suffered pain and was unable to walk as well as before. Mr. F. J. Frape, the defendant, said he was a fellow of the Council of Chiropodists and practised as a chiropodist and specialist in fitting shoes. He denied using force or causing pain; if Mrs. Colston had pain when she left his premises, she had pain when she came to him.

The county-court judge was assisted by the report of Mr. N. Capener, orthopædic surgeon of Exeter, upon the X-ray photographs which had been submitted during the trial. He asked Mr. Frape what was the explanation of the change indicated in the condition of the foot. The defendant replied that he could not say; his working upon the foot might have "upset a little stagnation." The judge held that Mrs. Colston had submitted to the treatment voluntarily, with the knowledge that Mr. Frape was a chiropodist and not a surgeon. Mr. Frape, he said, was a professional man of considerable skill who had done good work. He had advised Mrs. Colston that the toes required treatment and she had gone back to him for this purpose. But Mr. Frape had either been wrong in his diagnosis or in the action taken to remedy the trouble diagnosed; "if he did not know, he ought to have advised Mrs. Colston to see a doctor." The judge observed that he did not hold the chiropodist liable for the primary injury but for the advice he gave. Mrs. Colston was entitled to some damages. The judge limited the damages to those for the injury caused by the wrong treatment after the trouble arose; he awarded nothing for any unfortunate treatment which preceded it. And so, we see, a patient has herself to thank if she consults a chiropodist instead of an orthopædic surgeon; on the other hand the chiropodist is in no way prevented by law from practising manipulative surgery, but, if he ventures outside the field of the chiropodist in which he is highly skilled and experienced, he does so at some risk to himself as well as to the patient.

In England Now

A Running Commentary by Peripatetic Correspondents

A PERIPATETIC correspondent recently raised again the old question of crabbed age versus youth. From the internal evidence he was a young man with more than a touch of the arrogance and pitilessness of youth, but he will find in due time that age brings with it enough of disappointments, sorrows and disabilities, without adding to them the feeling that one is despised by one's juniors who are only waiting with impatience to step into one's shoes or to shovel one into the grave. The familiar jibe has again brought out that old men make wars whilst young men fight them, which means presumably that the men who survived the last war made this one and that most fathers do not mind the risk of their sons being killed, and which in any case is an absurdity in a country which chooses its rulers by universal suffrage. We were also of course reminded of Osler's dictum that a man is too old at 60 (or even 40), a rash statement which he regretted afterwards and which he refuted in his own person by living in full activity to the age of 70. Would it have been better for medicine if he had crept into his shell 10 years earlier? The fact, surely, is that the supposed antagonism between age and youth—like the alleged class-war or sex-war—is largely imaginary, for each period of life has its own special qualities: youth, energy and initiative; age, wisdom and experience. Edmund Waller took a kindlier and truer view when he wrote:

> The soul's dark cottage batter'd and decay'd
> Lets in new light through chinks that time hath made.
> Stronger by weakness, wiser men become
> As they draw near to their Eternal home.

The correspondent, I remember, then went on to advocate that most men should retire at 60, but prime ministers were to be allowed to go on to 65—a liberal concession which would have lost the country the present services of Mr. Churchill. There are two main reasons, however, which prevent men from retiring from work: one is that they can't afford to, and the other—and often the more potent—is the fear of boredom and of the general deterioration, physical and mental, which so often follows upon retirement; a mere limpet-like tenacity in clinging to office for its own sake is not common. It is of course right and only just to the juniors that a man should not stay on the staff of a hospital or in a teaching post too long, but a service limit is probably fairer all round than an age-limit. Under any system, however, it is inevitable that some members of the staff will be lost to the hospital while still at the height of their powers and others will stay on for years who had better have disappeared earlier.

* * *

For their increase in longevity the old are not to blame (unless they are all expected to commit suicide about the age of 70); it is largely the work of our profession and we must face its physical, just as governments will have to face its economic, consequences. Since the beginning of this century preventive medicine has been mainly occupied with the welfare of children and it is time that the old had their turn. We must supplement pædiatrics with geriatrics, a science of the diseases of age, and child psychology with senile psychology. It is astonishing how little most of us know of the peculiarities exhibited by disease in old people and of the best way of alleviating their many minor disabilities, and those who have the opportunity of acquiring such knowledge in institutions and hospitals for the chronically sick do not seem to pass their experience on to the profession at large.

Many old folk in all classes of life have, as every doctor knows, great difficulty in even keeping together a home in which they can die comfortably. In the days of large families there was usually an unmarried daughter who looked after the aged parents and this, though often hard on the daughter, at least enabled them to keep a home. But now the daughters are either married or have jobs of their own while the parents are too unselfish to keep them tied, and hence the number of unhappy and often querulous old people to be found in boarding-houses and private hotels, for many of them cannot afford the

1 Incision lateral, avoiding injury to vessels and nerves

2 Full exposure of both proximal and distal cut ends

3 The use of braided silk no 5 or 7 attached to a straight or rved needle of the "intestinal" type The suturing is ne very carefully so that there is no increase of diameter the site of suture, and the tied ends are buried between e cut ends of the tendon

4 At one time I tried to restore both the tendons and the eath, but it was obvious that the profundus and sublimis ndons fit so tightly within the sheath that a trivial adhesion sufficient to prevent function In recent years I have erefore departed from this in two particulars

(a) The sublimis tendon is removed for some distance oximal to the site of injury, retaining however the split rtion which gives passage to the profundus

(b) The sheath itself, all except the floor, is excised both ove and below the site of injury, with of course the proviso at the "pulleys" are not interfered with

Active movements are started immediately and, possible, maintained Sometimes however tissue action gives the impression that the above procedure a failure, but I find that if the patient returns to work r some weeks there is a gradual increase in elasticity nd coincident with this an increase in function If fter this waiting period there is little or no movement, en the finger is opened up again and adhesions severed, nd if scar tissue is too evident this is dissected out and e tendon itself covered with a paratenon graft from ver the triceps at the elbow

HE NEUROLOGICAL APPROACH TO MENTAL DISORDER

SIR,—It was a pity that Group Captain Symonds, in is presidential address to the psychiatric section of the oyal Society of Medicine, did not keep rigidly to his hosen title Difficult as was the task which he had thus et himself, he might nevertheless be sincerely congratuated on the skill with which he had marshalled facts, xperiments and theories in neurology which could have ny conceivable bearing on the problem But, unforunately for the complete success of his address, this did ot content him and he passed beyond his own specialty o a consideration and criticism of another science—iz , psychology—in which his knowledge and insight ere not up to the same standard Indeed he seems uite unaware of what modern psychology is, or of the xtent of its contributions to modern medicine, of a trictly scientific and verifiable nature The whole field f mental testing, the numerous psychological investiations into the building up of conditioned reflexes of very kind in the mental sphere, including the new inight reached thereby into the nature of suggestion and uggestibility and of the formation (as contrasted with he radical causation and meaning) of many neurotic ymptoms, and—at the other end of the scale—the facts nd theories of character types and the more philoophical problems of knowledge and will, are all of the utmost importance for modern neurological and psychiatrical theory but receive no consideration from him On the other hand he makes dogmatic statements about psychotherapy—i e , psychology as applied to the problems of medical treatment—which will be unhesitatingly rejected by every trained psychologist who has a medical qualification Psychology is becoming an ever more important and indispensable subject in the medical curriculum, with lessons for the general practitioner and for the specialist in every field, but in difficult cases there will always be a demand for highly specialised psychological treatment and highly trained psychotherapists

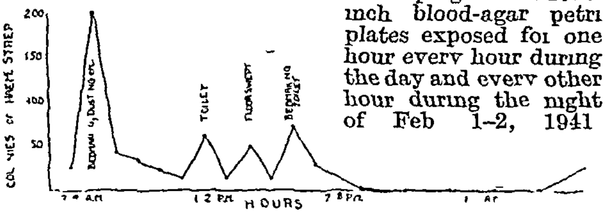
Oxford WILLIAM BROWN

SIR,—To an outsider it seems a pity, especially at the present time, that so much valuable space should be allotted to the disagreements of neurologists and psychoanalysts Further, it seems illogical that psychoanalysts, whose branch of psychology derives more than any other from neurology and neuropathology, should have chosen the rôle which they are playing Surely all but ultra-vitalists regard the nervous system as the *physical basis* of psychology, however inexplicable with our present knowledge the relationship may be Yet no neurologists can be so foolish as to underestimate the value of the contributions of pure psychologists, most of whom have had little or no training in neurology Just as astronomy made vast strides before Newton discovered the law of gravitation, so every branch of psychology elicited verifiable facts of theoretical and utilitarian value in spite of ignorance of neurology *At no time has psychology been so important to humanity* as now, and it behoves each branch to contribute its quotum of positive value, and so far as possible to coordinate the results Cannot the more moderate neurologists and psycho-analysts get together and segregate their points of agreement, leaving the more intransigent to plough their lonely furrows and prove their worth by the crops which they produce ?

Leeds J HERBERT PARSONS

INFECTED DUST

SIR,—The accompanying chart shows more graphically than words or figures can the effect of disturbing the dust in a single-bedded cell housing a boy convalescent from scarlet fever The chart was prepared from counts of the total number of colonies of hæmolytic streptococci developing on two four-inch blood-agar petri plates exposed for one hour every hour during the day and every other hour during the night of Feb 1–2, 1941



This boy was infected with a type-2 streptococcus on admission but a week later nose and throat swabs gave cultures of a type-3 streptococcus It was found on inquiry that in a cell on the opposite side of the corridor which separates two rows of cells was a patient—the only one—with a type-3 streptococcal throat infection The dust of her cubicle also contained the type-3 streptococcus, and further investigation indicated that this streptococcus gained access to the boy's respiratory tract by transfer and inhalation of the infected dust from the opposite cell Henceforth the boy's nose and throat cultures yielded streptococci of both types 2 and 3, while type 2 was usually more scantily represented than type 3 among colonies picked from "exposed" plates or cultured dust

FEEDING OF THE YOUNG

SIR,—I was most interested to see Professor Mottram's letter, written at a time when the problem of providing adequate first-class protein in the child's diet assumes even greater importance, and I should like to take this opportunity of voicing again my own fears and alarms Professor Mottram has given a figure of 30 g of first-class protein a day for the child of 9–10 years, and has shown that under present conditions the child of the middle class will barely achieve this amount, so that, he says the poor child is bound to suffer from a deficiency , it is only fair to say that this should not necessarily follow in circumstances where foods are rationed, since all children should be receiving their ration, but we know only too well, as Sir John Orr has said, that the protective foods are increasingly rationed by price, and it is clear that they will continue to be so until family allowances help to prevent such an anomaly Who could doubt this who has read the many recent careful studies of working-class diets—for example, that of Najib U Khan in Newcastle-upon-Tyne, in which it is recorded that in unemployed families the average consumption of fresh milk was less than ½ pint per man per week, or that of Dr T N V Potts on 205 families in the West Riding of Yorkshire, in which he showed the average consumption of fresh milk in all the families was not more than 2 pints per head per week, and in which he says "the average consumption of milk per head decreases as the number of young children in the family rises, so that the diets of the poorer groups of families are likely to be specially deficient in the so-called protective foods and more especially in those families which contain several young children "

Of all the administrative difficulties that beset the unwary in a hospital such as ours the difficulty of getting and keeping maids is perhaps the most trying, and certainly the most persistent Mere difficulty of securing an adequate nursing staff pales into insignificance beside this other major evil, an evil not, of course, peculiar to hospitals in these days but possessing for them such nightmarish urgency as threatens to bow down matron and her satellites, who are not easily bowed down We have looked for maids in all sorts of likely and unlikely places—labour exchanges, servants' registries, Women's Voluntary Services—and have enlisted the help of headmasters of schools and many others, often to no purpose Our failure cannot be ascribed to any lack of assiduity or perseverance, for we "would fish all day though not encouraged by a single nibble" Yet sometimes we do have our nibbles, and the catch is an extraordinary assortment of the too well educated, the not too well educated, the impudent, the fat, the angular and the unsophisticated (for a little), we have met them all Some of them have merely inquired about us, some have come and looked at us and gone away, a few have come and looked like staying Hospital life seems to appeal to a few of the more gregarious, but even that appeal sometimes becomes dimmed by the kind of work to which they are assigned There is comparative willingness to do ward maids' duties, but a dearth of applicants for work in the kitchen The process of educating such a varied assortment is naturally painful, doubtless painful for the maids, and often painful enough for their victims The supervision of maids is no easy task, calling for qualities of acidity and pugnacity, commonly only encountered in elderly spinsters The routine seems to be an unending round of roll-calls and remonstrances, homilies on polishes and breakages thinly interspersed with lessons in deportment

If it is difficult to obtain maids it is still more difficult to keep them Scarcely a month passes without some secession, and occasionally we encounter a phase of mass evacuation when whole battalions (or so it seems) threaten to down tools in a body and away like some burst of eruptive activity that threatens to throttle our whole domestic being The end of the month is a period of tribulation and of dread, of stock-taking and of retribution We then speculate on how many will leave us on the morning after next pay day The factors producing these major disturbances are sometimes wholly beyond our control, for a very minor incident in kitchen warfare can precipitate a crisis far-reaching in its effect and may lead to the defection of considerable cohorts Our geographical situation, remote from large centres of population, does little to commend us to our maids, and we are driven in self-defence to provide for their entertainment as liberally as we can in the hope that we may compensate in our amateurish way for the missing flesh-pots Certain it is that our maids are amongst the most regular attenders at our entertainments, as they are the most outspoken critics of our entertainers

* * *

I wonder whether the Dunmow flitch is to be offered this year Since 1244 it could be claimed by any pair who were prepared to swear at the end of their first year of married life that they had had no quarrel and had never wished the knot untied The kudos of winning used to be more important than the prize itself, and few thought it worth while to indulge in an orgy of marital bliss for a mere chunk of bacon But now the boot is on the other foot, what is fame compared with enough pig to last a small family for months? The flitch would be free, of course, but would it be couponless? If so the judges had better prepare for a rush of entries like an Irish sweepstake and we must look for a pandemic of nauseating sweetness in the home, at least when there are witnesses present

---

PHENOTHIAZINE has established itself in veterinary medicine as an anthelmintic with a low toxicity, and in our own columns (*Lancet*, 1940, 2, 808) Dr P H Manson-Bahr has described its application in human medicine to the treatment of threadworms I C I (Dyestuffs) Ltd inform us that they have made the drug readily accessible for this purpose in 1 gramme tablets A sweetened granule form containing 25% phenothiazine will also shortly be available for children

Letters to the Editor

AIR-RAID STRAIN IN MENTAL-HOSPITAL ADMISSIONS

SIR,—When assessing ætiological factors in cases admitted to this mental hospital, we have had to consider the possibility of air-raid strain as playing some part, since this is not infrequently suggested by relatives on the routine inquiry form I am therefore investigating all cases admitted since Oct 1, 1940, from this point of view, and hope to furnish a detailed report at some future date Meanwhile, the gist of an analysis of the first 200 cases may be of interest Air-raid strain as an ætiological factor was suggested in 25 (12½%) of the cases, but in only 2 (1%) was this regarded as of major importance and in 3 (1 5%) as partly contributory The former 2 cases have both recovered, and one of the latter group has departed much improved It is not therefore expected that there will be any burden on mental-hospital accommodation as a result of air raid strain

I would also like to record that although our hospital has a fair share of the noises on the South Coast, and on one occasion received a direct hit, the demeanour and behaviour of the 1200 patients has in no way been affected Occasionally there is a complaint about disturbed sleep at night, and a few patients still maintain that they will not get out of bed for Hitler or anybody else!

Knowle Mental Hospital, Fareham I ATKIN

A PSYCHIATRIC CASUALTY

SIR,—I have recently come across a type of case which must be very common in certain areas in these days of intensive and prolonged emotional stress and which should receive prompt recognition and treatment

A man of 38, single, was working as a fitter in a well known south coast port during August of last year His employers were working on Admiralty contract and he was engaged on this work During the course of his duties he suffered an injury to his back which incapacitated him for a fortnight, though no actual injury was ever demonstrated After this he returned to work and remained there with frequent interruptions due to hysterical "collapses" until Dec 26, when "conditions became intolerable" and he returned to his home in the north During this period (August to December) he was subjected to blitz conditions, and, to cut a long story short, there is little doubt that his final collapse and his present state are due to fear of bombing He naturally attributes his emotional state to his accident and is at much pains to convince all and sundry of his immunity from the consequences and effects of war in the air By reason of the nature of his work, he is apparently bound to return to the scene of his fears if he recovers, and so he is becoming a confirmed hysteric and he therefore requires intensive psychotherapy and rehabilitation

In my opinion this man is a psychological casualty of war and should be treated as such at a neuropsychiatric unit, but he is not eligible for treatment under the Emergency Medical Service—this would doubtless create a precedent! There must be many similar cases needing such specialised intensive treatment, who for lack of suitable provision are becoming economic dead weights to the community at a time when the community can ill afford such luxuries

Ryhope, Sunderland T M CUTHBERT

INJURIES TO TENDONS

SIR,—Your review (p 382) of "Surgery of Modern Warfare" (Part III), in discussing the suture of the flexor tendons of fingers and hand, states that if the sheath is involved the prognosis is hopeless In a recent discussion in the *British Medical Journal* the consensus of opinion was similar In a large glass works the medical officer is faced with divided tendons much more frequently than in other industries, and after various trials I have come to the conclusion that although the problem of the digital portion of the flexor tendon is a difficult one it is by no means insoluble Since in recent years I have had some measure of success, ranging from partial to full restoration of function, a summary of the technique employed may be of interest instead of 8s 6d with 6s 6d instead of 5s. on the first £165 of taxable income Income-tax will be payable on all incomes over £110, instead of £120 as at present, and this will bring another two million people into the taxable class The allowance for earned income is reduced from a sixth (maximum £250) to a tenth (maximum £150) and the personal allowance from £170 to £140 for married people and from £100 to £80 for others The extra tax paid because of the reduction in earned-income and personal allowances will be credited to the taxpayer in the Post Office Savings Bank at the end of the war, so that Mr Keynes's plan for compulsory savings has made its mark The same idea is seen in the concession by which 20% (less tax) of the excess profits duty paid will be set aside as a reserve for postwar reconstruction No change is made in allowances for children Where tax is deducted from salaries the new scale will take effect from Nov 1, for others it will apply to the instalment due on Jan 1, 1942 The Chancellor promised that the Government would extend the principle of stabilising the prices of essentials—including fuel and lighting—with additional subsidies where necessary The medicine stamp duties are to be repealed from Sept 2 and the Minister of Health will be introducing legislation " to maintain a fair balance between the interests of the pharmacists and of other vendors "

QUESTION TIME

Salaries for Nurses

In answer to a question the Minister of Health made the following statement The existing and prospective shortage of nurses in hospitals is giving rise to anxiety Thanks to the reinforcements provided by the Civil Nursing Reserve the emergency hospitals dealing with civil and military casualties are for the most part adequately staffed. Our main concern is with the hospitals which provide for the general needs of the civil population and in particular those dealing with infectious disease and the old and infirm Here the shortage is in some cases acute Available beds cannot be used on account of shortage of nurses, and staffs are carrying on under increasing difficulties To meet this situation, I propose to appeal to the women and girls of the country to enrol for nursing service in any part of the country. Those who join as nursing auxiliaries will not be sent to hospitals dealing with infectious disease or mental cases or to sanatoria, unless they volunteer for this service The appeal will be especially addressed to the age groups which are shortly to be registered

I wish to stress the importance of securing a larger number of women who are prepared to take up nursing as a life career Those who are prepared to join on this basis and accept training in the hospital allotted to them will receive salaries at the rate of £40 a year rising by annual increments of £5 It is proposed also to increase the salaries of members of the Civil Nursing Reserve in residential posts in hospitals The salaries for the assistant nurse and trained nurse include a sum representing the employer's contribution towards superannuation and the rates[1] will be

For nursing auxiliaries	£55 a year
For assistant nurses	£70 a year
For trained nurses	£105 a year

in each case with board, lodging and laundry and indoor and outdoor uniforms Those who respond to the appeal and are accepted will receive a guarantee of a year's employment and will be asked to undertake to serve for that period. Recruits who join as nursing auxiliaries will receive a short course of instruction in hospitals during which they will receive 10s a week as pocket money, together with board, lodging and laundry

The inter-departmental committee under the chairmanship of the Earl of Athlone made a number of important recommendations, consideration of which was deferred by the war Of these perhaps the most important related to the machinery for fixing the salaries and pensions of nurses on a national basis, and recommended the establishment of salaries committees for this purpose analogous to the Burnham committees in the teaching profession. I propose to take immediate steps to consult the various interests concerned with a view to establishing the necessary procedure This, however, will take time, and in the meantime it is in my view very desirable that hospital authorities should review the salaries now paid to their nursing staffs in the light of the new rates.

I have already on the staff of the Ministry at headquarters and in our regional offices 53 state registered nurses, partly recruited for the E M S services and partly engaged on the public health and hospital work of the department Arrangements have now been made for the whole of this work to be grouped on its professional side under the general direction of a chief nursing officer with two deputies I have appointed as chief nursing officer and chief matron of the Emergency Hospital Service Miss Katherine Watt, principal matron of the Emergency Medical Service One of the posts of deputy will, in my view, be most appropriately filled by the appointment of a nurse with current experience of hospital management, and I hope to make such an appointment at a very early date I also propose that the second deputy should be a nurse with special experience of public health and domiciliary nursing services I have asked the Parliamentary Secretary to make the nursing division her special concern. The Secretary of State for Scotland is making similar arrangements

Mr **RHYS DAVIES** Will the Minister bear in mind that a number of girls and women are willing to serve in hospitals if they are not thrust into nurses' homes ? Can they not engage in this service and go to the hospitals to do their day's work, going home in the evenings when their homes are near the hospital ?—Dr **SUMMERSKILL** Does the Minister realise that the new scales are not as high for a qualified nurse as a girl can receive in domestic service to day ?—Mr **BROWN** I have reason to believe that these scales will be regarded, taken as a whole and in the light of what I have stated, as a very great forward movement, and they will mean very heavy extra expense for all hospitals concerned as well as for the Government emergency scheme —Mr D **FRANKEL** Does the Minister realise the repercussions which this will have financially on the local authorities, and does he propose to make any subsidies to them ?—Mr **BROWN** I will take into consideration any representations that are made when the facts are brought out I am told that for the London County Council the suggested increase for nurses in all grades would involve an additional expenditure of £70,000 a year —Mrs. **AGNES HARDIE** Will the Minister consider training some men as nurses under the same wages and conditions ?—Dr **SUMMERSKILL** At £55 a year ?—Mr **BROWN** There are, of course, male nurses, and they do very valuable work for the patients in regard to whom their services are appropriate —Mr J **MCGOVERN** Are these wages intended to drive girls into munition work ?—Mr **BROWN** I have reason to believe that they will help to solve what has been one of the most difficult of our problems —Mrs H B **TATE** The Minister obviously comes within the definition of an optimist

Sir **STANLEY REED** Since many nurses marry and do not qualify for superannuation allowances, will the Minister consider a provident fund which would benefit both those who do their full term and those who retire before its completion ?—Mr **BROWN** That will be one of the long term questions to be discussed.

Superannuation of Service Nurses

Viscountess **ASTOR** asked the Secretary of State for War whether his attention had been called to the fact that voluntary-hospital nurses who were called up for duty in His Majesty's nursing services had either to lose a substantial part of their pension benefits by reducing their contributions to the superannuation scheme or to cease the contributions and convert their policy into a paid up assurance, or to pay contributions usually paid by their hospital as well as their own contributions , and whether, in view of the hardships imposed at present on nurses, he would arrange for the payment by the War Office of the employers' contributions —Captain H. D R. **MARGESSON** replied I have given careful consideration to the position under the Federated Superannuation Scheme of nurses from voluntary hospitals called up as members of the Queen Alexandra's Imperial Military Nursing Service Reserve or the Territorial Army Nursing Service, but I am afraid that it would not be practicable for the War Office to pay the employer's contribution towards superannuation benefits, which had previously been paid by the hospital. I am, however, reviewing the conditions of service in the nursing service, and I hope to be in a position to announce very shortly certain increases in pay which will help to meet the difficulty —Miss I. **WARD** In view of the fact that these negotiations have been going on for over 18

---

[1] Current rates of pay for nurses in the Civil Nursing Reserve employed in hospital are nursing auxiliaries £2 3s 6d a week (less board lodging and laundry) assistant nurses £64 2s a year (plus board lodging and laundry) trained nurses £99 2s a year (plus board lodging and laundry)

In my view the figure of 30 g daily of first-class protein for a child of 8–10 years is on the low side, even the B M A diet of 1933 gave a figure of 35 1 g, and the League of Nations 1936 report gives 44 g for a child of 6 years and 56 g for one of 12–14 years, say, 50 g for a child of 8–10 years My figures (*Publ Hlth*, April, 1939) showed that when rate of growth in children was correlated against the ratio of expenditure on first-class protein and energy foods (P/E) an improvement in the rate of growth occurred up to a ratio of 1 5, this being the highest ratio recorded, so that for a child of 8–10 years the weekly expenditure of 50 pence of the B M A 1933 diet should have been expended in the ratio 32 1/17 9 and not 23 5/26 5 as the diet suggested This would mean that even the B M A 1933 diet should have permitted 50 g a day and not 35 1 g as given But this is not the whole story, for further figures (*Publ Hlth*, July, 1939) have suggested that the B M A diet is itself not more than 64% of that which would provide the best rate of growth in children, and if this is the case even 50 g must not necessarily be looked on as the amount which nature would provide by choice It is not surprising, therefore, that the average rate of growth of a number of public schools was shown to be 53 8% greater than the average of elementary-school children

In these circumstances, therefore, special attention should be given to this problem and no effort should be spared to increase the amount of first-class protein available for our children In my view the best method is to increase the milk production and to import dried milk powder, both liquid and dried milks should be made available to families with children at reduced rates, so that not less than the equivalent of 1½ pints a day is consumed by every child This quantity of milk provides roughly 27 g of first-class protein, which may be taken as somewhere near half the amount necessary At the same time, of course, it will provide other valuable growth-promoting substances, such as the essential mineral elements calcium and phosphorus, which cannot be obtained so readily in any other way Another measure which might reasonably be taken would be to lower the age of the meat ration to perhaps 2 years so that the larger adult portion of meat is made available to all children In doing this we must not imagine for a moment that making the meat available is the same as providing it, since the larger families have not the means to purchase it even when it can be bought Can any time in our history be more propitious than this for introducing family allowances?

Warwick FRASER BROCKINGTON

SCOTLAND

PARATYPHOID IN THE HIGHLANDS

THE outbreak of paratyphoid B in the shires of Ross and Inverness has raised some interesting administrative problems although clinically the disease was familiar enough Frontal (or occipital) headache plus slight epistaxis left little doubt about diagnosis once the epidemic was recognised, and there was at least one case of intestinal hæmorrhage serious enough to require transfusion Nevertheless the mimicry of other diseases has led in places to some delay in notification The first case was diagnosed about six weeks ago near Tain in Ross-shire and the main incidence was in the eastern part of that county, particularly around Alness, where over 50 cases occurred in one practice Up to the time of writing some 40 cases have been reported at Inverness and a dozen at Nairn, isolated cases have turned up in remote spots The fever hospital at Strathpeffer has admitted more than 80 of the patients, the segregation regarded as essential by the health authority not always proving acceptable to the local gentry Sulphonamides have been used pretty freely in daily doses of 6 g or so without apparent effect on the course of the fever The distribution of the outbreak soon acquitted either water or milk as the vector, but the pastrycook is still under suspicion A salutary by-effect of the outbreak has been a recognition of the need for protecting institution staffs against falling victims to infection The less heroic members of the staff are, however, apt to compare the painful local reactions after inoculation with the apparently lesser discomfort of a mild attack of the disease

Parliament

IN the House of Lords on April 2 Lord HANKEY said that the three great pillars of the permanent civil research organisation of the Government were the Department of Scientific and Industrial Research, the Medical Research Council and the Agricultural Research Council Important research organisations also exist in the Admiralty, the Ministry of Supply, which undertakes most of the research work for the War Office, the Air Ministry and the Ministry of Home Security, while the Scientific Advisory Committee, of which Lord Hankey is chairman, links up through the Royal Society the great stream of outside research with these Government activities

Speaking of the work of the Medical Research Council Lord HANKEY said that in concert with the Ministry of Health preparations were made even before the war to safeguard public health against the risks of war conditions An Emergency Public Health Laboratory Service was established with laboratories all over the country so that any unusual outbreaks of disease might be rapidly identified Stocks of anti-sera and vaccines were accumulated and distributed throughout the country The application of research in nutrition usually lagged some fifteen years behind discovery But under pressure of war conditions the results of research are now being applied in many directions A stream of guidance is being issued to the public bringing out the importance of milk, potatoes and vegetables, which provide the essential vitamins and mineral salts in their natural and most effective form, and right methods of cooking A national wheatmeal bread, the result of concentrated emergency research, has been put on the market Lord HANKEY emphasised that the sphere of the Medical Research Council extends far beyond medicine as that term was generally understood It is concerned in all problems that affected man's health and efficiency. We are engaged in a death struggle, but Lord HANKEY held that our scientists are at least as good as those of Germany, and we are building a scientific equipment which is destined to play an ever-increasing part in our war effort and in the period of reconstruction which must follow

Sunday Opening

On All Fools Day the House of Commons discussed an order in council giving discretionary powers to local authorities to open on Sundays theatres and music halls where troops and changed industrial conditions created a special demand To a lively debate which, as Mr A P HERBERT said, showed sincerity and eloquence if not always Christianity, Sir FRANCIS FREMANTLE brought a whiff of scientific detachment when he claimed that the jazzification of the Sunday was a further inroad on the mental health of the nation The preservation of his Sunday rest was now especially important to the worker Mr HERBERT MORRISON who summed up said Parliament had had a day out of the ordinary rut and they were probably all the better for having had a free and independent discussion He pointed out that the regulation would end with the war and that it preserved local option He believed it would help to keep people cheerful and happy But on a free vote the order was annulled by 144 to 136

The Budget

The main aim of Sir KINGSLEY WOOD in the fourth war budget, which he introduced on April 7, has been to ward off inflation He puts our expenditure for the coming year at £4207 million (excluding the value of goods obtained from the United States under the Lease and Lend Act and payments to be made there for current orders), compared with the estimate of £3884 million for last year This total includes certain expenditure "covered by the gross balances of the Dominions and other countries," and the figure for domestic expenditure may be put at £3700 million Of this about £1600 million is expected to come from existing taxation, and the same sum from savings, leaving a gap of £500 million to be filled if inflation is to be avoided Half of this the Chancellor hopes to meet by increased savings, and the remaining £250 million is to be raised entirely from direct taxation The standard rate of income-tax will be 10*s* th a view to making it unnecessary for mothers with chil- en, who are ill and require attention, to stand for hours in eues ?—Mr BROWN I have been in consultation with the nister of Food, and I understand that he has under con- deration the special needs of young children for such foods

London Children killed by Enemy Action

In reply to a question Mr HERBERT MORRISON, Home cretary, said The number of children under sixteen killed enemy action in the whole of the London civil defence gion between Jan 1 and Feb 28 this year was 76 The mber injured and detained in hospital was 136

Obituary

DAVID DIAMOND

M R C P , D P H

Dr Diamond, deputy medical officer of health for Hull since 1939, has been killed in an air-raid on that city Since the outbreak of war he had been largely responsible for the A R P casualty services there and when he died he was on duty Dr Diamond was born in London but he spent part of his boyhood in South Africa and began his education there at the University of Cape Town He qualified M R C S from St Bartholomew's Hospital in 1923, and after holding some resident appointments he decided to take up public-health work He gained experience of handling men and affairs in Holborn and the Port of London and in 1931 he was appointed assistant medical officer of health for the Hull and Goole port authority The same year he obtained his D P H In 1934 he became senior assistant medical officer of health in charge of the tuberculosis department at Hull and his published work reflects his lively interest in the welfare and problems of the ex-tuberculous patient Dr Diamond leaves a widow and two young daughters

Notes, Comments and Abstracts

A LIBRARY SEEKS SANCTUARY

Sir D'Arcy Power, having decided it is no longer safe to have a collection of books under one roof in London, is offering his library for sale at Messrs Sotheby within the next few weeks The collection includes a series of some sixty or seventy editions of the Regimen Sanitatis Salerni, chiefly French, German and English a wonderful storehouse of popular dietetics from which came much of the information which is still in use, such as " The best Doctors are Dr Diet and Dr Quiet " It began life as a few hundred verses dedicated to the eldest son of William the Conqueror, though he never came to the throne It was copied over and over again in every European language each editor adding something of his own until when printing was introduced, it had become a substantial volume with woodcut illustrations. The collection was formed with the object of showing how successive editions had been enlarged

The library also contains most of the works of Osler and Harvey Cushing, many of which are autographed, and a series of unpublished letters from Dr Weir Mitchell about William Harvey Harvey and John Hunter are both well represented and there is a valuable collection of the writings of English surgeons of the sixteenth century The chef d'œuvre is a small volume date 1595 which Dr Bayley used to send as a Christmas present to his friends This volume has an inscription in Dr Bayley's handwriting when he presented it to the Lord Chief Justice of King James I and is therefore unique, for the name was not known and Bayley has signed this copy in full He was a fellow of New College Oxford and is buried in the ante-chapel The book deals with diseases of eyesight, and subsequent editions, considerably altered, were issued by his nephew, Dr Bannister There is also a copy of the 1552 edition of the " Woman's Book," which lacks the last page, and an autographed letter from that genial anatomist, Dr Oliver W Holmes sending a copy of " The Wonderful One-horse Shay "

PICTURES OF HEALTH

EDUCATION takes a short cut when it appeals to the eye The Central Council for Health Education have always kept this well in mind and in a new series of posters and leaflets they cover a remarkably wide tract of country. The eye tires quickly, so the posters are numerous and can be often changed , they are also by various artists, which means that the style has no chance to pall , and they show the advantages of exercise, cleanliness, of brushing your teeth, of fresh air and appropriate food from dozens of unexpected and attractive angles The captious might wish for a little more emphasis on the droll side of these activities—wit in a poster stamps it on the memory as an anecdote drives home the point of a lecture But they have every other quality to make them memorable and a few of them have fun too The health leaflets are pithy and easily assimilated They deal with diphtheria, measles, louse infestation, and purification of water-supplies, and are sold at cost price to local authorities for distribution by medical officers of health The council think it would be useful if they could also be displayed in the waiting-rooms of doctors and dentists, and are ready to suppply a limited number of free copies to those who apply to the secretary Tavistock House, London, W C 1

DOCTOR AND FARMER TOO

Prof Thomas Bodkin's godfather and uncle by marriage, Frank MacMahon, inherited an estate in the west of Ireland but his affairs did not prosper At the age of 40 he decided to become a doctor, qualified, and at Beauparc, co Kildare, combined general practice with farming to his own great content and to that of all with whom, professionally or otherwise, he came in contact He was a large man in every sense of the word, devoted no less to the sports and pastimes of the countryside than to his work, and idolised by his small godson who now writes of him with reverence and affection in a short but altogether charming book " My Uncle Frank " (Robert Hale 5s) is in no sense a biography ; it is a series months can the Minister say when he will be able to give decisions on the review ?—Captain Margesson I think the matter is coming to a head now

Removal from the Nursing Register

Mr R W Sorensen asked the Minister of Health whether he is aware that many hospital authorities refuse to employ fully qualified nurses, or to train probationers, who have been, or are, unmarried mothers , and, in view of the recent action of the General Nursing Council in removing the name of a nurse who was an unmarried mother from their register, whether he will take action to prevent unjust actions of this character ?—Mr Brown The answer to the first part of the question is No With regard to the second part of the question, an appeal lies to the High Court against a decision of the General Nursing Council to remove the name of a nurse from the register, and the matter is not one in which I have power to take any action —Mr Sorensen In many of these cases is it not morally reprehensible to exclude these women on those grounds, and will he do what he can to discourage it ? —Mr Brown That is a matter of opinion and conviction

Dr Edith Summerskill Does the Minister approve of the removal of a nurse from the register because she has had an illegitimate child in a case where it has not been proved that she has been guilty of professional misconduct with a patient ?—Mr Brown You are asking me to express an opinion upon what the court may or may not say about particular cases, and I must refuse to do that in the absence of any evidence about the cases —Dr Summerskill I am asking the Minister to express an opinion because the Ministry is represented on the General Nursing Council

Rehabilitation of Injured Workers

Mr T Magnay asked the Minister whether he is now able to make a statement on the steps proposed for securing that modern and properly organised treatment is provided for fracture cases occurring amongst industrial workers ?—Mr Brown The Secretary of State for Scotland and I have consulted the Minister of Labour and other Ministers concerned, and propose to provide for these cases as far as possible under the Emergency Hospital Scheme The hospital accommodation available under this scheme includes a large number of beds in hospitals and orthopædic centres which are, or will shortly be, specially equipped for dealing with cases of fracture In these hospitals and centres there are available, in addition to surgical skill of the highest class, the most modern forms of treatment by physiotherapy—including massage, electricity, and remedial exercises—and occupational therapy For the purpose of treating war casualties, both military and civil, these facilities are welded together into a comprehensive organisation, supervised by the consultants in orthopædic surgery employed by the Ministry of Health and the Department of Health for Scotland, so that the patients can be sent to the hospitals best suited for dealing with their injuries and, if necessary, transferred from one to another in the course of their treatment The treatment of casualties is and must remain the primary purpose of the Emergency Hospital Scheme But, in order to secure the fullest possible use of the organisation which has been provided, the Government have decided that in so far as there are vacant beds not likely to be required for the treatment of war casualties, they should be made available for fracture cases occurring amongst certain classes of the civil population whose early return to work is of special importance to the national cause Accordingly, cases of fracture sustained, whether in the course of their work or not, by manual workers engaged in any of the following employments, munition work—including ship building and ship repairing—building and civil engineering, mining, agriculture, fishing, public utility undertakings, shipping and transport, will be eligible for treatment in hospitals or centres under the emergency scheme Whole-time paid civil defence personnel will also be included in these arrangements As in the case of certain classes of the civil population who are under existing arrangements admitted to hospitals in the scheme for general treatment, the patient admitted under the new scheme will be expected to contribute through any contributory association to which he may belong, or, if he is not a member of such an association, to pay such amount as he can reasonably afford towards the cost of his treatment, according to ordinary hospital practice I may also add that the ordinary practice in Scottish hospitals will continue

Major Milner Will the same opportunities not be available for part time civil defence workers ?—Mr Brown No —

Sir Francis Fremantle Will these excellent arrangements be extended not only to fracture cases but to many other cases which require the same treatment and rehabilitation, and are equally important, and will the Minister avoid a duplicate organisation ?—Mr Brown There has been no duplicate organisation The number of first class hospitals with first class equipment and surgeons with special qualifications is limited What we have to do is to use these resources to the maximum extent in order to get those injured in industries vital to the war effort and whole time civil defence workers back to their posts at the earliest possible moment

Health of the A T S

In answer to a question Captain Margesson gave the following statement of the medical arrangements in the Auxiliary Territorial Service personnel who wish to report sick attend at the medical inspection room and can there receive outpatient treatment from the medical officer Reception stations are provided for detachments of 300 and upwards and sick bays are opened at medical inspection rooms for smaller units At reception stations, the medical officer, who may be a woman medical practitioner, has a staff including V A D nursing members and members of the A T S , and may have a sister or staff nurse, if required A T S orderlies are authorised in sick bays where the strength of the detachment is over 40 A wing for A T S patients has been established in a large military hospital near London, and there are A.T S wards in over 20 of the larger military hospitals Military families hospitals are also used for the A T S , and all the E M S hospitals are available for them There is an A T S convalescent depôt, and a Red Cross convalescent home is reserved for the use of women serving with the Forces Courses of lectures in hygiene have been arranged as part of the training of officers and other ranks

Replying to a further question Captain Margesson said that the decision to replace civilians by Royal Army Medical Corps women doctors where available on the panels formed to examine A T S recruits was taken partly because the method of payment of civilian doctors was unsatisfactory and partly to economise in medical personnel

Alien Doctors

In replying to a question Mr Brown said it was not intended to fix a maximum number of doctors who should have the benefit of the Medical Practitioners (Temporary Registration) Order, 1941 Up to date 28 doctors of enemy nationality have been selected for employment

Emergency Treatment of Insured Patients

In answer to a question Mr Brown stated that An insurance practitioner is required to make all necessary arrangements for securing the treatment of his insured patients where prevented from giving such treatment himself by urgency of other professional duties or other reasonable cause If neither the practitioner nor his deputy is available for giving treatment in case of accident or other sudden emergency, any other insurance practitioner who may be available can be required to give it A fee is payable to the last mentioned practitioner, subject to the claim being passed by the panel committee The fee is recoverable from the patient's own practitioner unless the panel committee are satisfied that there was reasonable cause for not summoning him

Night Rotas for Doctors

Mr Groves asked the Minister whether, either in areas which had sustained war damage or, generally, any scheme had been formulated or was in contemplation to enable groups of civilian doctors, by rotation, to be on duty at night for all purposes and thus permit the others to obtain relief and rest , and how many insurance committees favoured such an arrangement —Mr Brown replied In a number of areas a rota of doctors for duty at first aid posts, medical aid posts in public shelters, and food and rest centres has been arranged Similar arrangements for providing medical attention for insured persons is a matter for agreement between the panel committee and insurance committee of each area concerned, and detailed information is not available

Special Food for Children

Mr G Mander asked the Minister whether he will consider the advisability of making arrangements for special food, such as eggs and fruit, to be supplied to children needing it for health reasons, through the clinics or some public agency,

THE MODERN TROGLODYTE*

BY LORD HORDER, G C V O , F.R C P.
SULTING PHYSICIAN TO ST BARTHOLOMEW'S HOSPITAL LONDON, CHAIRMAN OF THE COMMITTEE ON HEALTH CONDITIONS IN AIR-RAID SHELTERS

AT the outset of this address I want to pay a tribute that vast and anonymous body of men and women o, by remaining in their homes, have reduced the oblem of public air-raid shelters to much smaller mensions than would otherwise have been the case, and ve thus contributed greatly to its solution The inister of Home Security has given these people his ed of praise I should like to add my own These k have obeyed the Minister's exhortation to "dispersal", they have braved the "blitz" above ground, ith the aid of one or other form of domestic protection, they have been busy during the night with their civil fence jobs, with their nursing, their doctoring and eir administrative duties as I say, no praise can be o high for them

EVOLUTION OF THE SHELTER

I don't propose today to discuss controversial matters, r with things as they might have been Things rarely e what they might have been As I remember it, ere was a demand made from several quarters, that the overnment should do something about deep bombroof shelters After a period of conference between the xperts this demand met with a reply which was, in fect a statement of policy, a policy which we now now as "dispersal" It was first clearly defined in 938 It was to be implemented through the local uthorities, by the provision of steel shelters (later called Andersons") for domestic use, strutted basements, ommunal shelters, trenches, subsidiary buildings which ight have a peace-time value, compulsory shelters in onnexion with new buildings and shelters for persons caught in the street"

Let us be frank. Most of us were widely off the mark n our estimate both of the particular nature of the peril, ts results upon life and property, and the reaction of many of the people Those enormous number of asualties which many of us visualised did not, thank od, occur But the damage to our homes far exceeded nything that we foresaw And so when, in August and eptember of last year, the air-raids came in all their ury, we were faced simultaneously with two results for hich we were quite unprepared a large number of omeless people who wanted some sort of protection and an even larger number who, losing all faith in their homes, whether they had, or had not, some form of domestic shelter, ran to earth There is a point past which, in times *of crisis the people will not drill* Policy or no policy, these two masses of people streamed into any underground shelter that seemed to them to be safe "*Seemed* to be safe," I said because, again and again, they chose places which were quite insecure and not infrequently under such military objectives as overhead railway stations and the like They tramped long distances to reach the shelter of their faith, ofttimes this was a haven that was traditional from the last war They queued up outside in the rain as it frequently was, and later in the snow, carrying their bedding and various articles needed for the night This they did day after day, an hour or so before the "blitz" was expected For, instead of the casual and temporary protection by day which had been met by the provision of surface public and communal domestic shelters in which people might sit or stand, the nightly air-raid attacks called for all-night dormitory protection For this the surface shelters were not adapted But nor were the large underground shelters of the people's own choice Thus there arose, and quickly attained alarming proportions, a situation full of hygienic hazards

ABUSE OF THE PROTECTIVE PRINCIPLE

The serious risks to the common health were early recognised by the two central authorities concerned An investigating and advisory committee undertook a rapid survey, reported and made a series of recommendations There were two outstanding facts a state of gross overcrowding and its being, as yet, nobody's job to so condition these places as to make them fit for habitation Some confusion as between the three authorities involved—the ministries, the regional commissioners and the borough officials—was perhaps inevitable That the onus eventually lay with the local authorities was accepted but the serious restriction of personnel and material imposed a tiresome lag upon the implementation of the recommendations mentioned

So that though at the centre guidance and assurance of financial responsibility were quickly forthcoming, at the periphery execution was tardy "Priority" was pleaded to an extent which harmonised rather badly with our reiterated assurance to the civilians that they were "in the front rank" The test of our democratic system of local government was a severe one, and we were too nervous of giving the new concept of regionalisation full play, fearing a clash between these two interests The nervousness was uncalled for, as nervousness generally is for the appointment of Alderman Key as regional commissioner, with shelters as his special work, has been a marked success Complications arose from the fact that some of the largest places chosen by the public for night shelter were private property, which had been invaded willy-nilly In one such place, though the local authority was making slow and entirely inadequate provision, or rather improvision, for sanitation, the cleansing jobs were done—again, and of necessity, inadequately—by the staff of the company owning the property. This gratuitous work, a real bit of national service, was rewarded one morning by the receipt of a notice from the borough sanitary inspector pointing out that a nuisance was being committed by the firm in question!

In a certain provincial centre the owners, or lessees, of a large rambling disused place of entertainment did a good trade by letting out shelter accommodation at so much a week. The only part of the place which could be reasonably regarded as relatively secure was the basement This had been a "chamber of horrors" Perhaps it was this fact and the paintings of horrific subjects on the wall which dictated the price at this level at 2*s* 6*d* On the ground floor the price ranged from 5*s* to 10*s* On the first floor, where security was reduced to nil, you might get a small suite for a guinea A devoted cure acted as cicerone because he knew the intricacies of the place better than anyone else

In another city, which, though very vulnerable, only suffered night raids, a large shelter under a school was full of people, with a pathetic proportion of children, during the afternoon, and a continuous series of entertainment went on

In still another town, whose industry has completely disappeared, a disused railway tunnel had been converted into an underground street, and a mean street at that and the tendency for the population to become residential was increasing "Blitz" or no "blitz" the children did not see the sun, or even the daylight, for days together and the old and infirm came to the surface less often still

I could easily increase these examples of abuses of the principle of protection which led the advisory committee to recommend that all places used as public shelters should be recognised and scheduled or be disallowed. *Recognition* was to entail a standard of security as laid down by the Ministry of Home Security and the possibility of being so conditioned as to be free from danger to the *public health* The situation had however, got quickly into such arrears that, even with the provision of alternative shelter, due notice of what was intended and *posters stating that* what was being done was in the general interest, no little trepidation seized the hearts of some of the authorities on the eve of the closure of the condemned shelter (Certain political capital, *too*, was, in some places, made out of the situation) These fears turned out to be groundless, the people were quite of sketches displaying some of the facets of a sturdy and attractive character and affording also more than a glimpse of a vanished Ireland It is possible that Professor Bodkin views his own early youth through rose-coloured spectacles Be that as it may, call it escapism if you must, there will be many who will be glad to share his view of the spacious and leisurely days at the beginning of the present troubled century

* Read before the Royal Society of Arts on April 2

AN X-RAY STRETCHER

PHILIPS METALIX have designed a new piece of X-ray apparatus which consists of a stretcher trolley combined with a Bucky table It is a link between the non-mobile and mobile types of unit, and is therefore of value to a hospital with limited means which cannot afford an all-services apparatus but wants more finished radiographic work than is given by the ordinary mobile set The makers claim that with the stretcher radiography of weight-bearing joints, skull radiography and pelvimetry may be satisfactorily performed

It is doubtful, however, whether the ordinary mobile set has sufficient output to provide the necessary penetration for a lateral radiogram of the spine or pelvis, and the quality of the work will necessarily be limited by these factors The Bucky table may be raised or lowered 9 in and adjusted at any position from the horizontal to the vertical The apparatus is a compromise and is unsuitable for specialised skull work, but for ordinary routine radiography it should be a useful adjunct to a mobile set

Copies of the glossary of psychological terms (see THE LANCET, March 29, p 424) prepared by the brain-injuries committee of the Medical Research Council may be had (price 1*d*) from H M Stationery Office or through any bookseller

Appointments

KEER, K J T, M R C S examining factory surgeon for Wickham Market, Suffolk

KELF H D, M R C S, D P H temp asst M O H (A R P) for Portsmouth

PRINGLE, G H, M R C S, D P H M O H and school M O for Bridgwater, and assistant county M O for Somerset

RAYNER, M M -S, M B Camb, D P M asst physician at the Cassel Hospital for Functional and Nervous Diseases

SHOULMAN, RAHUM, L R C P temp resident asst M O at the borough isolation hospital, Bolton

Births, Marriages and Deaths

BIRTHS

ANDERSON —On March 29, at Exeter, the wife of Surgeon Lieut - Commander E W Anderson, R N V R —a son

MACFIE —On March 31, at Alexandria, the wife of Major W Gordon Macfie, R A M C —a son

MOORE —On March 31, in London, the wife of Mr A M A Moore, F R C S — a daughter

NEWSOM —On April 2, at Johannesburg, the wife of Dr R A Newsom, Northern Rhodesian Medical Service—a daughter

PHILP —On March 30 at Boscombe, Bournemouth, the wife of Captain R A Philp, R A M C —a daughter

SPOONER —On April 3, at Cambridge, the wife of Flying Officer W H C Spooner, R A F V R of Blandford, Dorset—a son

THOMPSON —On April 2, at Market Harborough, the wife of Dr J F Thompson—a daughter

MARRIAGES

FELLOWS—THRUPP —On Feb 26, in Birmingham, Joseph William Edward Fellows, M B, lieutenant R A M C, to Cecile Patricia Thrupp, M R C S

WAY—CORSON —On April 4, at Pennal Geoffrey Leslie Way, M R C S, captain R A M C, to Edith Mairi Reid Corson

DEATHS

BEACH —On April 3, at Reading, Thomas Boswall Beach, C M G, C B E, M R C S, colonel A M S

DUNN —On April 3, at Bengeo, Hertford, Robert Ayton Dunn M D, B Hy Durh, D P H, formerly medical officer of health for Hertford

HAJEK —On April 3, at Dalcham Gardens, N W 3, Markus Hajek, formerly professor of laryngology in the University of Vienna, aged 79

HARTIGAN —On April 3, Thomas Hartigan, M D Durh, Lancaster Close W 2, aged 70

HOGG —On April 3, at Iverna Court, Kensington, Frederick Stanley Hogg, L R C P E

TURNER —On April 7, at Hove, Sir George Robertson Turner, K B E, C B, F R C S, surgeon rear admiral, 1914-18, aged 85

Infectious Disease in England and Wales

WEEK ENDED MARCH 29

Notifications —The following cases of infectious disease were notified during the week smallpox, 0, scarlet fever, 1212, whooping-cough, 4440, diphtheria, 1038, enteric fever, 20, measles (excluding rubella), 14,589, pneumonia (primary or influenzal), 1264, puerperal pyrexia, 154, cerebrospinal fever, 319, poliomyelitis, 3, polio-encephalitis, 2, encephalitis lethargica, 5, dysentery, 140, ophthalmia neonatorum, 79 No case of cholera, plague or typhus fever was notified during the week

Deaths —In 126 great towns there was no death from smallpox or scarlet fever, 1 from enteric fever, 39 (2) from whooping-cough, 20 (1) from measles, 30 (1) from diphtheria, 30 (4) from diarrhœa and enteritis under 2 years, and 87 (9) from influenza The figures in parentheses are those for London itself

Newcastle on Tyne reported the fatal case of enteric fever There were 7 deaths from whooping cough at Liverpool, 6 at Birmingham, and in the same week Glasgow reported 13

The number of stillbirths notified during the week was 247 (corresponding to a rate of 46 per thousand total births), including 15 in London

it

many folks consider him. It is one of my chief regrets in this business that we had no time in which to make an extensive census of some of the large public shelters, not merely as to where the people came from but exactly why they were there. As it is we know that shelterers are mainly composed of three groups:

(i) There are those who have no homes because they have been bombed out; these should, as we know, go to rest centres and not to public shelters, but people have a way of not doing what they should, and for a number of reasons, some of which are very good reasons. This group is now much smaller that it previously was because the people forming it are being rehoused in increasing numbers.

(ii) The second group includes those shelterers whose homes have no protection within or without, or whose "Andersons" have become uninhabitable, or whose communal domestic shelters have no amenities.

(iii) The third group of poorer people generally speaking, include those who, whether by birth or status or race or type, are unable to stand up to the terror of the "blitz" and the noise that is incident to it.

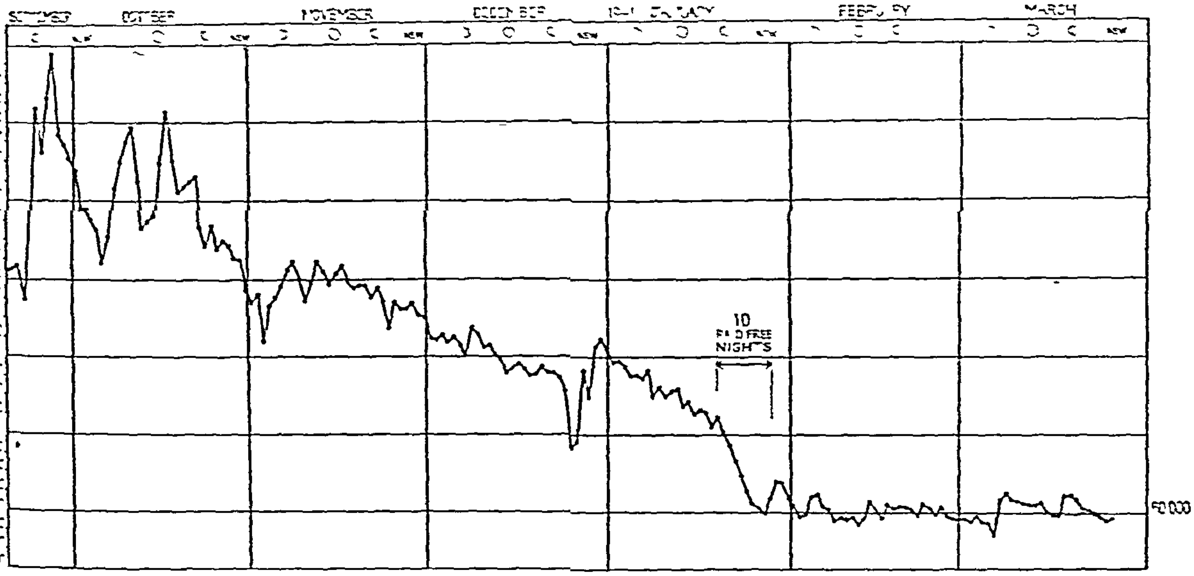
There is always a hard core of person who cannot stand up against fear and noise. We hear a lot about "foreigners and Jews" who crowd into the shelters. They certainly do. But these folk are British citizens or are under British protection. We must give them as much security as we can and we must care for them. That is where we differ from the Nazis. In doing this we show them that stability, a sense of security and neighbourly kindliness are qualities which characterise life in our particular Commonwealth. There is no better way in which to demonstrate the British habit of "live and let live" than this; nor need any priggishness enter into the business of this common humanity in face of extreme peril and great discomfort.

"Great discomfort"; yes. Most of these people work by day; sleep is essential to all work; broken nights make work impossible.

HIS OTHER HOME

But what does it mean when the comfortably housed shelter visitor expresses surprise at the queer places and attitudes in which many of these folk get their sleep? And that they are not only patient but good humoured in the midst of beastly surroundings? It means that there is, alas, too little difference between their nights in the large public shelters last September and their nights in their own homes. This great and cataclysmal upheaval has brought into the shelters for our inspection the slum conditions of which we *said* we were heartily ashamed and which but for the war we were rapidly changing. Is it to be wondered at, therefore, that for many of these citizens the conditions that we have now been able to establish represent for them better and, what is equally significant, happier ones than those they had before the night bombing began?

This is a terrible indictment of what is sometimes, and ironically, called "our social system." But it is true. These folk enjoy a communal life, though of a rudimentary sort, which breeds a spirit of good temper and dignity; it enables them to adapt themselves to the nation's exigency with spirit, and the net effect upon their morale is good. It is a superficial, entirely theoretical and an erroneous view to take of the mass of shelterers that their morale is poor. That it should have needed a war, and life underground for half the twenty-four hours, to achieve a result which is bringing joy to the hearts of our social workers, is a humiliating thought. Yet such is the case. The mood of these people is plastic and they offer a field for health education as never before. They have, and they appreciate, free medical aid. The mothers submit to the shelter doctor's persuasive argument about diphtheria immunisation when the visit to the clinic for this purpose would never be made. The nurse is listened to with attention and her ministrations are gratefully received. The troglodyte wants to be fit. It intrigues him to know how. To get *among* the ordinary folk and give them sane, simple and homely advice—why this has been the dream of doctors with any vision for the past hundred years! Here is field work of the best kind in preventive medicine—to keep the fit fit and to make the near-to-fit fit.



ESTIMATED NUMBER OF PERSONS SHELTERING AT TUBE STATIONS
(including Bethnal Green, Liverpool Street and Aldwych Stations)

DEMOCRACY IN ACTION

A great blot on all this is the position of the children. They should all be away in the country. True, they remain surprisingly healthy, and they behave amazingly well. But these facts do not condone their presence in places which, only by a near miss, have been made hygienically possible. Priestley in one of his recent broadcasts stressed the fact that the national emergency is throwing up leaders. We see men and women taking the lead in this communal shelter life: the level-headed motherly woman, caring for her companions and undertaking for them; the resourceful humorous man who, as shelter warden, secures obedience with a minimum of grousing. Democracy in action, this, and the best possible refutation of its alleged decadence.

The shelterers want, and they get, their own music and their own culture. This culture is real and is good, different though it often is from the culture we sometimes try to impose upon them from outside. We have not encouraged, and we still resist, attempts to force any willing to be guided by hands that showed themselves to be firm as well as wise

PRIMARY DANGERS HEADED OFF

Slowly but surely the primary dangers were headed off The burden of the work fell upon the borough medical officers of health, who have been key men in the situation throughout, the engineers, and the Regional Commissioners and their staffs To the energy of the Shelter Policy Committee of the Ministry of Home Security, under the active chairmanship of Miss Ellen Wilkinson, a great deal is owing Much credit is also due to the Ministry of Health Inspection Committee under Dr P G Stock A number of voluntary bodies have pulled their weight The two ministers, Mr Herbert Morrison and Mr Malcolm MacDonald, holding this amongst their other and even heavier responsibilities, were constantly at close grips with the problem, and both of them showed an urbanity which remained unbroken by the usual receipt of many more kicks than ha'pence A great administrator once said that "expediency is the object of all statesmanship," and that "political action is good or bad according to its consistency, not with theory, but with circumstance" The shelter problem has been a good example of this dictum

Certain guiding principles may be mentioned Those "optimum standards," which make such a strong appeal, were quite unattainable We had to start with minimal standards and improve on these gradually as time and the necessary personnel and materials allowed The limitations of the experts were exposed Some of them hadn't seen the conditions with which we were struggling, and, again, they wanted time to undertake more research into the questions we asked them But time, though the pursuit of science does not usually take much cognisance of it, is vital when we are applying science to the life of man Time was just what we couldn't give We wanted the help of science at the present moment of its development, not as the result of future experiment, so that we might adapt it to these special conditions Some of our expert colleagues were very trying The nearest thing to a public shelter was a canal barge, said one of them, to whom I had appealed on some point, but, he added, reflectively, "a public shelter is *not* a canal barge", so he couldn't make a suggestion

Two concurrent policies had to be constantly kept in view—a short-term policy, by which first-aid was applied to the grosser insanitary conditions so as to reduce these as quickly as possible, and a long-term policy, by which the largest and most unhygienic shelters, where the chief dangers lay, might be gradually unloaded as alternative underground protection could be found, or as the people could be weaned from mother earth and induced to disperse themselves in their domestic shelters or in domestic communal shelters which they could be persuaded to make sufficiently attractive As the autumn and winter approached the problem was further complicated by the fact that many "Andersons" were put out of action by flooding Almost all the trench shelters were uninhabitable for the same reason, quite apart from their being ill adapted to dormitory use Thousands of surface brick shelters, from lack of amenities, did not function during the night, and, indeed, were little used by day

Gradually the more augean of the conditions resulting from the first few weeks of arrears were changed, not in the record time achieved by Hercules, nor by the same method, but still changed Bunking the shelters got the people off the ground, made sleep more possible for them, and spaced them out Sanitary arrangements and regular cleansing were introduced, soft earth floors were covered by cement or asphalt, ventilation and lighting were improved The tube railway system was an early, and a justifiably favoured, place of shelter The chairman and staff of the London Passenger Transport Board deserve much credit for their labours in conditioning the stations and certain unused portions of the tunnels Amongst their efforts the system of exhaust plant for the cleanly disposal of the sewage and the admirable series of medical aid posts which, as agents of the Ministry of Health, they installed, should be specially mentioned

A number of large private firms acted with similar promptness and enterprise, providing excellent dormitory accommodation for their own staffs and also for the public I reiterate that there is no such thing as an "ideal" or "model" large underground public shelter But some of these shelters under big industrial business premises come as near to justifying these terms as possible

THE ABSENCE OF ILLNESS

Despite the dangers that seemed to face us, not only have the anticipated epidemics and illnesses not arrived, the health, not only of the shelterers, but of the whole community, has remained remarkably good A boy fell from the top tier of a bunk and ruptured his spleen, and a woman fell on to the track of the railway and was killed But those are not shelter diseases, "shelter diseases," as such, have not appeared What is perhaps even more remarkable, even lice and bugs have been difficult to find, yet at one time the question of airing, cleaning and disinfecting the shelterers' bedclothes gave us a great deal of anxious thought As for the country as a whole, there has been just as much diphtheria as we deserve, seeing that we will not immunise our children, and the usual seasonal outbreak of measles, though not of a virulent kind The influenza curve scarcely reached a level which we could dignify by the term "epidemic," and the main seasonal incidence of this pest is, as already stated, now over Cerebrospinal fever (meningitis) is the one disease that has shown an increase, the cases reaching a higher figure than during any year since 1915 Even so, the figure is not an alarming one

Public health authorities are puzzled to know the reasons of this robust state of the nation's health I hear that a small committee is being formed to inquire into this unusual and unexpected state of affairs Various guesses have been made as to the factors mainly responsible for the relative immunity we are enjoying Is it due to a better state of nutrition of the people? Or to their greater dispersal? Or, where shelterers are concerned, have they really lived under better conditions, perhaps, than they do in their own homes—more, not less, fresh air, less heated atmospheres, and regular exercise twice a day going to and from the shelters? (When I think of the number of ventilators I have myself opened, braving both looks and language, I can believe that more, and cooler, air may have something to do with it!) We do not know Perhaps several, or all, of these features have operated But we must remember that there are unknown elements in the very determination of epidemics The causes of a rise and fall in the virulence of a bacterium or a virus so far escape us You cannot *start* an epidemic by bad conditions, but if an epidemic *does* start, then bad conditions affect both the number of cases of the disease that occur and the severity of them

How much, or how little, of all our work has really been necessary, therefore, we shall never know Such ultimates are hidden from us Incentive to action lies in seeing a thing to do and seeing it clearly We make our contribution in proportion as we do it promptly and thoroughly

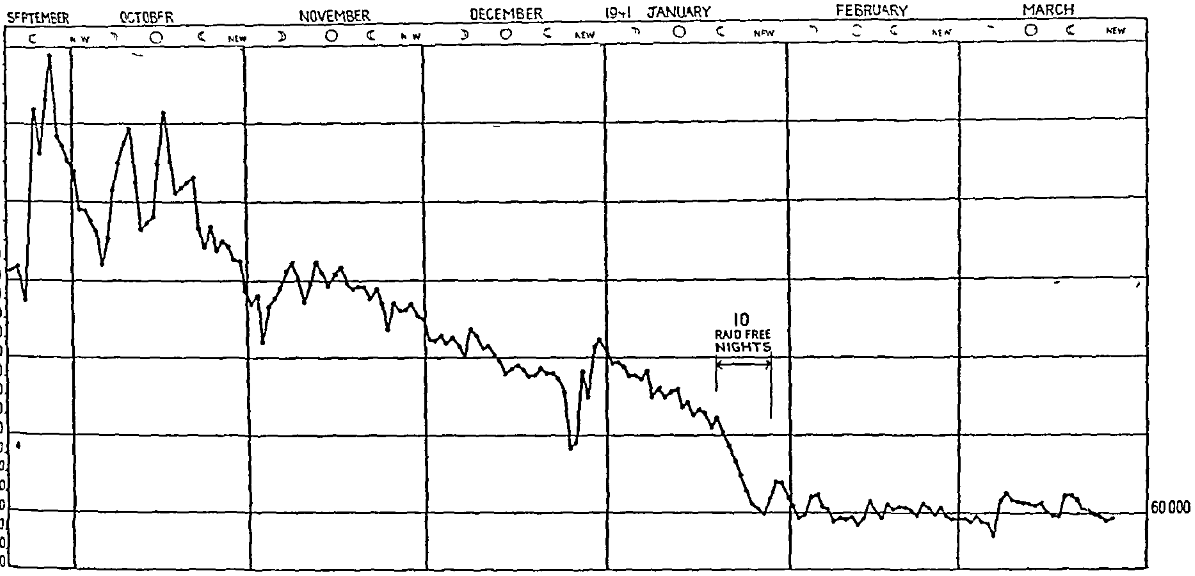
THE SHELTERER HIMSELF

I began by paying a tribute to those people who "stayed put" in their homes or at their posts For those who have stayed in their beds and without bothering about protection, though my own lazy temperament leads me to have some sympathy with them, my reason denies them my praise At heart we are an indolent race, we hate to take pains, even though it be to avoid disaster We take the easy path Some of us make a virtue of this or our friends often read our inertia as virtue, calling us courageous But courage is an *active*, not a passive, trait Then there are some folk who say they don't mind dying, as though *merely* to die, without getting a decent return for our life, is praiseworthy It is, as the Roman said, sweet to die for one's country if the sacrifice is demanded, otherwise it is sweeter still to live for one's country, though sometimes this is more difficult

You may gather from these remarks that I do not disdain the modern troglodyte merely because he takes trouble to protect himself I want to know a great deal more about him before I think him reprehensible, as any folks consider him. It is one of my chief regrets in is business that we had no time in which to make an tensive census of some of the large public shelters, ot merely as to where the people came from, but actly why they were there. As it is, we know that elterers are mainly composed of three groups:

(i) There are those who have no homes because they have een bombed out; these should, as we know, go to rest centres nd not to public shelters; but people have a way of not oing what they should, and for a number of reasons, some of hich are very good reasons. This group is now much smaller at it previously was because the people forming it are being housed in increasing numbers.

(ii) The second group includes those shelterers whose omes have no protection within or without, or whose "Andersons" have become uninhabitable, or whose communal domestic shelters have no amenities.



ESTIMATED NUMBER OF PERSONS SHELTERING AT TUBE STATIONS
(including Bethnal Green, Liverpool Street and Aldwych Stations)

(iii) The third group, of poorer people generally speaking, include those who, whether by birth or status or race or type, are unable to stand up to the terror of the "blitz" and the noise that is incident to it.

There is always a hard core of person who cannot stand up against fear and noise. We hear a lot about "foreigners and Jews" who crowd into the shelters. They certainly do. But these folk are British citizens or are under British protection. We must give them as much security as we can, and we must care for them. That is where we differ from the Nazis. In doing this we show them that stability, a sense of security and neighbourly kindliness are qualities which characterise life in our particular Commonwealth. There is no better way in which to demonstrate the British habit of "live and let live" than this, nor need any priggishness enter into the business of this common humanity in face of extreme peril and great discomfort.

"Great discomfort", yes. Most of these people work by day; sleep is essential to all work; broken nights make work impossible.

HIS OTHER HOME

But what does it mean when the comfortably housed shelter visitor expresses surprise at the queer places and attitudes in which many of these folk get their sleep? And that they are not only patient but good humoured in the midst of beastly surroundings? It means that there is, alas, too little difference between their nights in the large public shelters last September and their nights in their own homes. This great and cataclysmal upheaval has brought into the shelters for our inspection the slum conditions of which we *said* we were heartily ashamed and which, but for the war, we were rapidly changing. Is it to be wondered at, therefore, that for many of these citizens the conditions that we have now been able to establish represent for them better and, what is equally significant, happier ones than those they had before the night bombing began?

This is a terrible indictment of what is sometimes, and ironically, called "our social system." But it is true. These folk enjoy a communal life, though of a rudimentary sort, which breeds a spirit of good temper and dignity; it enables them to adapt themselves to the nation's exigency with spirit, and the net effect upon their morale is good. It is a superficial, entirely theoretical, and an erroneous view to take of the mass of shelterers that their morale is poor. That it should have needed a war, and life underground for half the twenty-four hours, to achieve a result which is bringing joy to the hearts of our social workers, is a humiliating thought. Yet such is the case. The mood of these people is plastic, and they offer a field for health education as never before. They have, and they appreciate, free medical aid. The mothers submit to the shelter doctor's persuasive argument about diphtheria immunisation when the visit to the clinic for this purpose would never be made. The nurse is listened to with attention and her ministrations are gratefully received. The troglodyte wants to be fit. It intrigues him to know how. To get *among* the ordinary folk and give them sane, simple and homely advice—why, this has been the dream of doctors with any vision for the past hundred years! Here is field work of the best kind in preventive medicine—to keep the fit fit and to make the near-to-fit fit.

DEMOCRACY IN ACTION

A great blot on all this is the position of the children. They should all be away in the country. True, they remain surprisingly healthy, and they behave amazingly well. But these facts do not condone their presence in places which, only by a near miss, have been made hygienically possible. Priestley, in one of his recent broadcasts, stressed the fact that the national emergency is throwing up leaders. We see men and women taking the lead in this communal shelter life: the level-headed, motherly woman, caring for her companions and undertaking for them; the resourceful, humorous man who, as shelter warden, secures obedience with a minimum of grousing. Democracy in action, this, and the best possible refutation of its alleged decadence.

The shelterers want, and they get, their own music and their own culture. This culture is real and is good, different though it often is from the culture we sometimes try to impose upon them from outside. We have not encouraged, and we still resist, attempts to force any willing to be guided by hands that showed themselves to be firm as well as wise

PRIMARY DANGERS HEADED OFF

Slowly but surely the primary dangers were headed off The burden of the work fell upon the borough medical officers of health, who have been key men in the situation throughout, the engineers, and the Regional Commissioners and their staffs To the energy of the Shelter Policy Committee of the Ministry of Home Security, under the active chairmanship of Miss Ellen Wilkinson, a great deal is owing Much credit is also due to the Ministry of Health Inspection Committee under Dr P G Stock A number of voluntary bodies have pulled their weight The two ministers, Mr Herbert Morrison and Mr Malcolm MacDonald, holding this amongst their other and even heavier responsibilities, were constantly at close grips with the problem, and both of them showed an urbanity which remained unbroken by the usual receipt of many more kicks than ha'pence A great administrator once said that "expediency is the object of all statesmanship," and that "political action is good or bad according to its consistency, not with theory, but with circumstance" The shelter problem has been a good example of this *dictum*

Certain guiding principles may be mentioned Those "optimum standards," which make such a strong appeal, were quite unattainable We had to start with minimal standards and improve on these gradually as time and the necessary personnel and materials allowed. The limitations of the experts were exposed Some of them hadn't seen the conditions with which we were struggling, and, again, they wanted time to undertake more research into the questions we asked them But time, though the pursuit of science does not usually take much cognisance of it, is vital when we are applying science to the life of man Time was just what we couldn't give We wanted the help of science at the present moment of its development, not as the result of future experiment, so that we might adapt it to these special conditions Some of our expert colleagues were very trying The nearest thing to a public shelter was a canal barge, said one of them, to whom I had appealed on some point, but, he added, reflectively, "a public shelter is *not* a canal barge", so he couldn't make a suggestion

Two concurrent policies had to be constantly kept in view—a short-term policy, by which first-aid was applied to the grosser insanitary conditions so as to reduce these as quickly as possible, and a long-term policy, by which the largest and most unhygienic shelters, where the chief dangers lay, might be gradually unloaded as alternative underground protection could be found, or as the people could be weaned from mother earth and induced to disperse themselves in their domestic shelters or in domestic communal shelters which they could be persuaded to make sufficiently attractive As the autumn and winter approached the problem was further complicated by the fact that many "Andersons" were put out of action by flooding Almost all the trench shelters were uninhabitable for the same reason, quite apart from their being ill adapted to dormitory use Thousands of surface brick shelters, from lack of amenities, did not function during the night, and, indeed, were little used by day

Gradually the more augean of the conditions resulting from the first few weeks of arrears were changed, not in the record time achieved by Hercules, nor by the same method, but still changed Bunking the shelters got the people off the ground, made sleep more possible for them, and spaced them out Sanitary arrangements and regular cleansing were introduced, soft earth floors were covered by cement or asphalt, ventilation and lighting were improved The tube railway system was an early, and a justifiably favoured, place of shelter The chairman and staff of the London Passenger Transport Board deserve much credit for their labours in conditioning the stations and certain unused portions of the tunnels Amongst their efforts the system of exhaust plant for the cleanly disposal of the sewage and the admirable series of medical aid posts which, as agents of the Ministry of Health, they installed, should be specially mentioned A number of large private firms acted with promptness and enterprise, providing excellent dormitory accommodation for their own staffs and also for the public. I reiterate that there is no such thing as an "ideal" or "model" large underground public shelter But some of these shelters under big industrial business premises come as near to justifying these terms as possible

THE ABSENCE OF ILLNESS

Despite the dangers that seemed to face us, not only have the anticipated epidemics and illnesses not arrived, the health, not only of the shelterers, but of the whole community, has remained remarkably good A boy fell from the top tier of a bunk and ruptured his spleen, and a woman fell on to the track of the railway and was killed But those are not shelter diseases, "shelter diseases," as such, have not appeared What is perhaps even more remarkable, even lice and bugs have been difficult to find, yet at one time the question of airing, cleaning and disinfecting the shelterers' bedclothes gave us a great deal of anxious thought As for the country as a whole, there has been just as much diphtheria as we deserve, seeing that we will not immunise our children, and the usual seasonal outbreak of measles, though not of a virulent kind The influenza curve scarcely reached a level which we could dignify by the term "epidemic," and the main seasonal incidence of this pest is, as already stated, now over Cerebrospinal fever (meningitis) is the one disease that has shown an increase, the cases reaching a higher figure than during any year since 1915 Even so, the figure is not an alarming one

Public health authorities are puzzled to know the reasons of this robust state of the nation's health I hear that a small committee is being formed to inquire into this unusual and unexpected state of affairs Various guesses have been made as to the factors mainly responsible for the relative immunity we are enjoying Is it due to a better state of nutrition of the people? Or to their greater dispersal? Or, where shelterers are concerned, have they really lived under better conditions, perhaps, than they do in their own homes—more, not less, fresh air, less heated atmospheres, and regular exercise twice a day going to and from the shelters? (When I think of the number of ventilators I have myself opened, braving both looks and language, I can believe *that more, and cooler, air may have something to do with it!*) We do not know Perhaps several, or all, of these features have operated But we must remember that there are unknown elements in the very determination of epidemics The causes of a rise and fall in the virulence of a bacterium or a virus so far escape us You cannot *start* an epidemic by bad conditions, but if an epidemic *does* start, then bad conditions affect both the number of cases of the disease that occur and the severity of them

How much, or how little, of all our work has really been necessary, therefore, we shall never know Such ultimates are hidden from us Incentive to action lies in seeing a thing to do and seeing it clearly We make our contribution in proportion as we do it promptly and thoroughly

THE SHELTERER HIMSELF

I began by paying a tribute to those people who "stayed put" in their homes or at their posts For those who have stayed in their beds and without bothering about protection, though my own lazy temperament leads me to have some sympathy with them, my reason denies them my praise At heart we are an indolent race, we hate to take pains, even though it be to avoid disaster We take the easy path Some of us make a virtue of this or our friends often read our inertia as virtue, calling us courageous But courage is an active, not a passive, trait Then there are some folk who say they don't mind dying, as though *merely* to die, without getting a decent return for our life, is praiseworthy It is, as the Roman said, sweet to die for one's country if the sacrifice is demanded, otherwise it is sweeter still to live for one's country, though sometimes this is more difficult

You may gather from these remarks that I do not disdain the modern troglodyte merely because he takes trouble to protect himself I want to know a great deal more about him before I think him reprehensible, as anterior aspect of the neck, and sometimes in the conjunctivæ and soft palate (present in case 2) *Lungs* often show the usual signs of death from asphyxia Subpleural hæmorrhages are seen, the lungs appear voluminous, cyanotic and œdematous On section, areas of congestion and œdema intermingle with aerated areas Microscopically the alveoli contain inflammatory exudate, red cells and leucocytes With appropriate staining many emboli are seen in the arterioles and capillaries *Brain* there is usually some congestion of the meninges and the brain substance On section a large number of petechial hæmorrhages are seen scattered throughout the white matter especially in the region of the centrum ovale Microscopically, fat-emboli can be demonstrated in the arterioles and capillaries in all parts of the central nervous system The petechial areas show a fat-embolus filling a small arteriole, around which is a circular zone of necrotic brain tissue, again surrounded by a circular zone of extravasated red cells *Heart* streaky hæmorrhages are often seen beneath the serous pericardium and in the substance of the myocardium Microscopically, small fat emboli can be seen filling the arterioles and capillaries in these areas and causing minute hæmorrhagic infarcts *Kidneys* systemic fat emboli invariably involve the kidney, though they usually do not show any characteristic changes microscopically Large snakelike emboli are often seen filling the capillaries of the glomeruli on microscopic examination

SYMPTOMS AND PHYSICAL SIGNS
